

Living Evidence Profile #6.4

(8 July 2022)

Question

What is the best available evidence related to the monkeypox outbreak?

What we found

To inform current knowledge related to monkeypox, we identified evidence, as well as experiences from 11 countries (Australia, Belgium, France, Germany, Italy, Netherlands, Portugal, Spain, Sweden, United Kingdom (U.K.), and the United States (U.S.) (see Box 1 for a description of our approach), and from all Canadian provinces and territories. While this living evidence profile focuses on monkeypox in humans, a complementary living evidence profile summarizes the best available evidence related to monkeypox in animals. We organized our findings using the framework below, which has not changed from the first version of our LEP.

Organizing framework

- Biology
- Epidemiology (including transmission)
- Prevention and control
- Clinical presentation
- Diagnosis
- Prognosis
- Treatment

We identified 13 new evidence documents since the last update of this LEP, of which we deemed 12 to be highly relevant. The newly added highly relevant evidence documents include:

- one guideline;
- three protocols; and
- eight single studies.

This LEP also includes evidence documents from the previous version that we deemed to still be highly relevant, for a total of 64 highly relevant documents.

Box 1: Our approach

We identified evidence published from 2017 onwards (to capture any evidence related to recent outbreaks outside Africa) addressing the question by searching Health Systems Evidence (HSE), Health Evidence, ACCESSSS, PROSPERO (review protocols and registered titles), PubMed and MedRxiv on 4 July 2022. We identified jurisdictional experiences by hand searching government and stakeholder websites. We selected 11 countries (Australia, Belgium, France, Germany, Italy, Netherlands, Portugal, Spain, Sweden, United Kingdom, and the United States) that are non-endemic for monkeypox and that have had recent documented cases.

We searched for guidelines, full systematic reviews (or review-derived products such as overviews of systematic reviews), rapid reviews, protocols for systematic reviews, and titles/questions for systematic reviews or rapid reviews that have been identified as either being conducted or prioritized to be conducted.

We appraised the methodological quality of full systematic reviews and rapid reviews that were deemed to be highly relevant using AMSTAR. Note that quality appraisal scores for rapid reviews are often lower because of the methodological shortcuts that need to be taken to accommodate compressed timeframes. AMSTAR rates overall quality on a scale of 0 to 11, where 11/11 represents a review of the highest quality. It is important to note that the AMSTAR tool was developed to assess reviews focused on clinical interventions, so not all criteria apply to systematic reviews pertaining to delivery, financial or governance arrangements within health systems or to broader social systems. We appraised the quality of the highly relevant guidelines using three domains in AGREE II (stakeholder involvement, rigour of development, and editorial independence) and classified guidelines as high quality if they were scored as 60% or higher on each domain.

This update to the living evidence profile was prepared in the equivalent of three days of a 'full-court press' by all involved staff.

We outline in narrative form below our key findings related to the question from highly relevant evidence documents, and based on experiences from other countries. This is accompanied by Table 1 that provides a summary of the total number of evidence documents in each domain of the organizing framework (with the number of new documents identified in brackets) and Table 2, which provides more details about key findings from each of the newly identified evidence documents and new insights from the jurisdictional scans. In Table 3, we provide findings from highly relevant evidence documents and jurisdictional scans from the previous version of our LEP.

A detailed summary of our methods is provided in Appendix 1, and the full list of newly identified evidence documents (including those deemed of medium and low relevance) is in Appendix 2a. The previously included documents are listed in Appendix 2b. Note that we summarized key points from each of the highly relevant evidence documents in Appendix 2b, but only the title and the URL are listed for those deemed to be medium or low relevance. We included the hyperlinks of excluded documents (at the final stage of reviewing) in Appendix 3. We also provide detailed summaries of knowledge related to monkeypox from other countries in Appendix 4, and from Canadian provinces and territories in Appendix 5.

Key findings from highly relevant evidence sources

Confirmed cases of monkeypox continue to rise globally since the last update on the available evidence. As of 22 June 2022, the [WHO reported 3,413 laboratory confirmed cases](#) and one death from 50 countries, which is likely an underestimate in the number of confirmed cases. For instance, the [U.S. CDC global map and case count](#) reported that there are 7,243 confirmed cases as of 6 July 2022. Most cases have been reported in the European region in case counts from WHO and the U.S. CDC.(2) Overall, the public-health risk at the global level is moderate according to the WHO, which continues to remain unchanged since the last update. However, the risk within the European region is high. In response to the increasing case count of the multinational monkeypox outbreak, the WHO released their latest [public-health advice for gatherings](#).(3)

We found and categorized two single studies related to the biology of monkeypox, where one study described the [phylogenomic characterization analysis](#) that showed signs of potential monkeypox human adaptation and the other study reported on [techniques for genome sequencing](#).(4,5)

Additionally, we found four single studies related to the epidemiology (including transmission) of monkeypox. These findings include:

- a [single study](#) which reported on the creation of an open-access database to track the incidence of monkeypox across multiple countries (published 1 July 2022);(6)
- a [modelling study](#) (pre-print) which simulated the spread of monkeypox in a hypothetical metropolitan area and found that the monkeypox virus may spill over from high-risk groups to broader populations, but could be reduced by at least 65% through public-health measures (e.g., quarantine, contact tracing) (published 29 June 2022);(7)
- another [modelling study](#) that simulated a population of 50 million people with socioeconomic and demographic characteristics of a high-income European country, found public-health measures such as contact tracing and ‘ring vaccination’ (i.e., vaccinating close contacts of exposed persons) could largely reduce the number of cases (published 23 June);(8) and
- a [single study](#) (pre-print) that described the findings of an online survey completed by 856 U.S. residents about their knowledge, attitudes, and perceptions about monkeypox, found that most respondents relied on information from healthcare professionals and officials, that almost half of the respondents felt that their knowledge level about monkeypox is poor or very poor, and that

current COVID-19 vaccination status was a strong predictor of positive intentions of receiving a monkeypox vaccination if recommended (published 23 June 2022).(9)

In addition, we identified three protocols for reviews currently underway on topics related to the epidemiology of monkeypox, which focus on: 1) the [epidemiology of monkeypox](#) (estimated completion 8 July 2022); 2) [global epidemiological and clinical characteristics of monkey cases since 1970](#) (estimated completion 16 July 2022); and 3) [prevalence of monkeypox transmission by sexual contact transmission](#) (estimated completion 30 July 2022).

Related to prevention and control of the monkeypox outbreak, a [non-systematic review](#) reported on the efficacy of disinfectants against monkeypox virus, and a [single study](#) conducted in the U.S. provided further evidence to suggest that the estimated mean incubation period aligns with the recommended 21 days for monitoring or quarantining close contacts (published 28 and 21 June 2022, respectively).(10,11)

Research evidence continues to emerge for equity-deserving populations. A low-quality [guideline](#) described a clinical-management algorithm for pregnant people with suspected monkeypox virus exposure, and the authors recommended that cases should be reported to the WHO and for clinicians to consider Tecovirimat and vaccinia immune globulin for pregnant people with severe illness (published 2 July 2022).(12)

Key findings from the jurisdictional scan

Key findings from the jurisdictional scan are summarized below according to each of the categories in the organizing framework.

Epidemiology (including transmission)

Similar to the available evidence, case numbers for monkeypox continue to grow across non-endemic countries identified in the jurisdictional scan. The Public Health Agency of Canada reported a total of [358 cases of monkeypox in Canadian provinces and territories as of 6 July 2022](#), with 236 cases confirmed in Québec, 101 cases in Ontario, 13 in British Columbia, and eight cases in Alberta. Case numbers rose to [1,385](#) in Germany as of 7 July 2022, [1,351](#) in the UK as of 4 July 2022, approximately [1,200](#) in Spain as of 1 July 2022, [605](#) in the U.S. as of 6 July 2022, [577](#) in France as of 5 July 2022, [415](#) in Portugal as of 1 July 2022, [168](#) in Belgium as of 6 July 2022, [28](#) in Sweden, and [17](#) in Australia as of 6 July 2022.(13-19)

Characterizations about the transmission and severity of the monkeypox outbreak made by jurisdictions continue to evolve. On [4 July 2022](#), the Public Health Agency of Canada (PHAC) noted that the possibility and extent of respiratory transmission of monkeypox is “unclear at this time.”(13) In the UK, the four public-health agencies agreed that the [current outbreak of monkeypox does not classify as a high-consequence infectious disease](#) given that there has been no observed mortality in the UK and there are interventions available.(2) Efforts to monitor the spread of the virus continues, with the UK Health Security Agency publishing an updated [epidemiological overview of the current monkeypox outbreak](#) every Tuesday and Friday and releasing a [technical briefing investigating the monkeypox outbreak in England](#).(13,20-22)

Clinical presentation

Clinical presentations of monkeypox continue to present in ways that are characteristic of the current outbreak, and atypical of clinical presentations in countries in which the virus is endemic. In France, the most commonly reported symptoms are a genito-anal rash, eruption on another part of the body, fever, and lymphadenopathy.(18)

Prevention and control

Jurisdictions are continuing to acquire smallpox vaccines to address the ongoing monkeypox outbreak. In a news conference, Canada's Chief Public Health Officer, Dr. Theresa Tam, indicated that [negotiations are underway to procure more monkeypox vaccine](#) from the Danish manufacturer Bavarian Nordic, who said in early June that PHAC had agreed to a US\$56 million, five-year contract to purchase IMVAMUNE vaccine, with expected delivery beginning in 2023.(23) In Spain, the Health Minister, Carolina Daria stated that Spain has "a significant amount" of vaccines available, [5,300 were acquired through the EU's Health Response \(HERA\)](#), and 200 from Imvanex that were purchased from another European country.(17)

As countries continue to secure, stockpile, distribute and administer smallpox vaccines to protect against monkeypox, jurisdictions are developing or updating guidelines for post-exposure prophylaxis (PEP) and pre-exposure prophylaxis (PrEP). In Ontario, for example, a [report by the Ontario Ministry of Health](#) dated 14 June 2022 provides Imvamune guidelines for healthcare providers, providing an overview of the use of Imvamune in special populations.(24) The UK Health Security Agency released a [monkeypox vaccination strategy](#) on 21 June 2022 that outlines priorities for targeted pre-exposure vaccination, occupational vaccination, and post-exposure vaccination, including for gay, bisexual and other men who have sex with men at highest risk based on markers of high-risk behavior, health workers who care for monkeypox patients, staff at sexual health clinics designated to assess suspected cases, staff at laboratories where pox viruses are handled, and staff responsible for decontamination around cases of monkeypox.(25) The French National Authority for Health published a [press release](#) outlining their vaccine strategy for two population groups: 1) those who have been vaccinated against smallpox in their childhood; and 2) children.(26) The government of Australia has also released [guidance on vaccination against monkeypox](#).(27)

As case numbers grow across jurisdictions, additional guidance to reduce transmission in the community and in healthcare settings are being released. For example, the UK Health Security Agency has published [guidance regarding planning events and mass gatherings](#) during the current monkeypox outbreak.(28) It has also updated [case and contact management](#) to indicate that cases do not need to be contacted every day but will rather be provided with contact details if they require support or develop symptoms.(14) Moreover, it produced guidance [regarding reducing risk of virus transmission at post-exposure vaccination clinics](#).(29) In Germany, RKI published a [recommendation](#) for the management of close contacts of monkeypox cases, which includes quarantining of individuals with a high risk of transmission, such as household members.(30) Finally, the Provincial Infection Control Network of British Columbia has released [interim infection prevention and control guidance for monkeypox in healthcare settings](#).(31)

Treatment

While jurisdictions continue to note that monkeypox is mostly treated through supportive care, many jurisdictions are securing and stockpiling potentially effective treatments for more severe

cases. For example, the [U.S. CDC](#) states that although there is no treatment available specifically for monkeypox infections, there are medical counter measures available through the Strategic National Stockpile (SNS) (although with limited available evidence on its effectiveness for the treatment of monkeypox) such as: 1) Tecovirimat; 2) Vaccinia Immune Globulin Intravenous (VIGIV); 3) Cidofovir; and 4) Brincidofovir.(32)

Table 1: Overview of topics related to monkeypox addressed by all included evidence documents (newly added documents in brackets)

Type of evidence document	Total*	Biology	Epidemiology (including transmission)	Prevention and control	Clinical presentation	Diagnosis	Prognosis	Treatment
Guidelines (non-robust)	1	-	-	-	1	-	1	1
Full systematic reviews	3	-	2	-	1	1	1	1
Rapid reviews	0	-	-	-	-	-	-	-
Non-systematic reviews	17	4	14	8	5	6	2	3
Protocols for reviews or rapid reviews that are underway	13	-	5 (3)	2	8 (1)	-	-	1
Titles/questions for reviews that are being planned	0	-	-	-	-	-	-	-
Single studies	80	12 (2)	40 (4)	17 (2)	18	10 (1)	8	14

*Some documents were tagged in more than one category so the column total does not match the total number of documents.

(n) = newly added evidence documents

Table 2: Highlights from new highly relevant evidence documents and jurisdictional experiences

Organizing framework domain	New evidence	New experiences
Biology	<ul style="list-style-type: none"> • A single study reported that a mutational analysis showed signs of potential monkeypox human adaptation in ongoing microevolution (Published 24 June 2022) • A single study evaluated the performance and added value of the MinION real-time TGS sequencing device for sequencing the complete genome of a MPXV strain, and concluded that the data obtained from directly sequencing DNA extracted from a lesion is sufficient to complete the genome of the virus (Published 24 June 2022) 	<ul style="list-style-type: none"> • None identified
Epidemiology (including transmission)	<ul style="list-style-type: none"> • A single study reported on the creation of an open-access database to track the incidence of monkeypox across multiple countries <ul style="list-style-type: none"> ○ Working with the WHO Hub for Pandemic and Epidemic Intelligence, the team is defining a contact data schema allowing countries and researchers to estimate key epidemiological parameters such as incubation period and serial interval across various settings (Published 1 July 2022) • A modelling study (pre-print) simulated the spread of monkeypox in a hypothetical metropolitan area (including high- and low-risk transmission among humans and animals to humans), which found that the monkeypox virus may spill over from high-risk groups to broader populations if transmission increases within the high-risk group but could be reduced by at least 65% through public-health measures (e.g., quarantine, contact tracing) (Published 29 June 2022) • A modelling study simulated a population of 50 million people with socioeconomic and demographic characteristics of a high-income European country <ul style="list-style-type: none"> ○ The baseline scenario projected that with no public health emergency interventions, monkeypox could lead to small national outbreaks of moderate duration, but 	<ul style="list-style-type: none"> • The Public Health Agency of Canada reported a total of 358 cases of monkeypox in Canadian provinces and territories as of 6 July 2022, with 236 cases confirmed in Québec, 101 cases in Ontario, 13 in British Columbia, and eight cases in Alberta • In an announcement on 4 July 2022, the Public Health Agency of Canada (PHAC) noted that the possibility and extent of respiratory transmission is of monkeypox is “unclear at this time” • As of 4 July 2022, the government of Australia has reported 17 confirmed cases of monkeypox, including five in Victoria, 11 in New South Wales, and one in South Australia • As of 6 July 2022, Belgium has reported a total of 168 Monkeypox cases within the country • As of 5 July 2022, there have been 577 confirmed cases of Monkeypox in France, with 387 reported in Ile-de-France, 52 reported in Auvergne-Rhône-Alpes, 37 reported in Occitanie, 30 in New Aquitaine, eight in Normandie, 23 in Hauts-de-France, one in Centre-val de Loire, four in Pays-de-la-Loire, 21 in Provence-Alpes-Côte d'Azur, three in Bourgogne-Franche-Comté, six in Grand-Est, and five in Brittany • As of 7 July 2022, there are 1,385 confirmed cases of Monkeypox across all 16 federal states in Germany • As of 1 July 2022, Portugal has reported 415 confirmed cases

	<p>they would all subside in 23 to 37 weeks, depending on the number of cases introduced</p> <ul style="list-style-type: none"> ○ Contact tracing with isolation of symptomatic cases would reduce the number of secondary cases by 72.2% following the introduction of 3 cases, 66.1% after 30 cases, and 68.9% after 300 cases ○ Adding ring vaccination to contact tracing would reduce the number of secondary cases by 77.8% following the introduction of 3 cases, 78.7% after 30 cases, and 86.1% after 300 cases (Published 23 June) <ul style="list-style-type: none"> ● A single study (pre-print) reported on the findings of an online survey completed by 856 U.S. residents (51% female, 41% with a college degree or higher, 38% were 55 years or older) about their knowledge, attitudes, and perceptions about monkeypox <ul style="list-style-type: none"> ○ The respondents reported that the most reliable information came from healthcare professionals, health officials (e.g., Centers for Disease Control and Prevention), and social media accounts of healthcare professionals and researchers ○ Almost half the respondents (47%) feel that their knowledge level about monkeypox is poor or very poor ○ Current COVID-19 vaccination status was a strong predictor of positive intentions of receiving a monkeypox vaccination if recommended ○ The low levels of knowledge about monkeypox indicate the need for more clear communication about the outbreak (Published 23 June 2022) 	<ul style="list-style-type: none"> ● As of 1 July 2022, the Public Health Agency has confirmed around 1,200 cases of orthopoxvirus in Spain, with Madrid and Catalonia are the most affected ● According to the U.S. Centers for Disease Control and Prevention’s 2022 Monkeypox Outbreak Global Map, Sweden has confirmed 28 cases of monkeypox as of 5 July 2022 ● As of 6 July 2022, the U.S. has reported a total of 605 confirmed monkeypox cases ● As of 4 July 2022, there are 1,351 cases of monkeypox in the UK ● The public health agencies of the four UK nations have agreed that the current outbreak clade of monkeypox does not classify as a high consequence infectious disease given that there has been no observed mortality in the UK and there are interventions available <ul style="list-style-type: none"> ○ However, importation of monkeypox directly from West Africa and cases caused by the Congo basin clade will still be classified as high consequence infectious diseases ● The UK Health Security Agency is publishing an updated epidemiological overview of the current monkeypox outbreak every Tuesday and Friday; the report includes information regarding the nation, region, and age of new cases ● The UK Health Security Agency has published a technical briefing investigating the monkeypox outbreak in England which contains sections about the following: <ul style="list-style-type: none"> ○ Assessed level of the outbreak in England ○ Research and evidence gaps prioritisation ○ Epidemiologic update, including findings from rapid sexual health questionnaires completed by cases ○ Transmission dynamics
Clinical presentation	<ul style="list-style-type: none"> ● None identified 	<ul style="list-style-type: none"> ● Of the cases investigated in France, the most commonly reported symptoms are a genito-anal rash, eruption on another part of the body, fever, and lymphadenopathy
Prevention and control	<ul style="list-style-type: none"> ● A non-systematic review reported that vaccinia viruses can be inactivated on artificially contaminated surfaces by 70% ethanol (≤ 1 minute), 0.2% peracetic acid (≤ 10 min) and 1% to 10% of a probiotic cleaner (1 h) <ul style="list-style-type: none"> ○ Hydrogen peroxide (14.4%) and iodine (0.04% - 1%) were effective in suspension tests, sodium hypochlorite 	<ul style="list-style-type: none"> ● Canada’s Chief Public Health Officer, Dr. Theresa Tam, indicated that negotiations are underway to procure more monkeypox vaccine from the Danish manufacturer Bavarian Nordic <ul style="list-style-type: none"> ○ The manufacturer said in early June that PHAC had agreed to a US\$56 million, five-year contract to purchase IMVAMUNE vaccine, with expected delivery beginning in 2023

	<p>(0.25% - 2.5%; 1 min), 2% glutaraldehyde (10 min) and 0.55% ortho-phthalaldehyde (5 min) were effective on artificially contaminated surfaces</p> <ul style="list-style-type: none"> ○ Copper (99.9%) was equally effective against vaccinia virus and monkeypox virus in 3 minutes (Published 28 June 2022) ● A single study (pre-print) estimated the incubation period from 22 cases (from 17 May 2022 to 6 June 2022) to be 7.6 days (from exposure to first symptom onset, 95% CI 17.1 days), which the authors concluded that it aligns with the U.S. CDC recommendation of monitoring for 21 days after last exposure (Published 21 June 2022) 	<ul style="list-style-type: none"> ● According to a Canadian 4 July 2022 news report, a total of 8,101 doses of IMVAMUNE vaccine have been administered in Québec since 27 May, and as of 30 June, nearly 6,000 people in Toronto have been vaccinated against monkeypox ● In Alberta, the Imvamune vaccine is currently being offered to those to have had close contact with someone who has monkeypox up to 14 days after exposure <ul style="list-style-type: none"> ○ As of 4 July 2022, eight people in Alberta are reported to have been immunized with the Imvamune vaccine ● A report by the Ontario Ministry of Health dated 14 June 2022 provides Imvamune guidelines for healthcare providers <ul style="list-style-type: none"> ○ The report provides an overview of using Imvamune in special populations: clinical trials have included people living with HIV, there is less experience in individuals with severe immunosuppression; no clinical trials have been conducted in pregnant individuals, although approximately 300 pregnancies have been reported to the manufacturer with no safety issues, and there is no data on whether the vaccine is excreted in breastmilk although this is unlikely since the vaccine is nonreplicating; the vaccine has not been studied in youth under 18 although it has been given to children as PEP in the U.K. for monkeypox; people with atopic dermatitis may have more intense and frequent reactions after vaccination ● The Provincial Infection Control Network of British Columbia has released interim infection prevention and control guidance for monkeypox in health care settings <ul style="list-style-type: none"> ○ The document outlines specific guidance regarding patient placement, hand hygiene, personal protective equipment, patient transport, cleaning and disinfection, laundry, and waste management ● The government of Australia has made the ACAM2000™ smallpox vaccine available to be used for PEP (e.g., healthcare workers, household contacts, or contacts in other settings) and PrEP (e.g., healthcare workers, laboratory worker), but cannot be used in individuals with severely immunocompromised conditions, people who are pregnant, people with active eczema or other active skin conditions, people with allergies, and children under 12 months
Diagnosis	<ul style="list-style-type: none"> ● A single study (pre-print) described the potential use of a real-time PCR assay in the multi-national outbreak given 	<ul style="list-style-type: none"> ● None identified

	its ability to detect positive test samples (Last updated 23 June 2022)	
Prognosis	<ul style="list-style-type: none"> • A low-quality guideline described a clinical management algorithm for people who are pregnant with suspected monkeypox virus exposure, and recommended that all cases of monkeypox virus in pregnancy are reported to WHO and an international registry for emerging pathogens, as well as clinicians to consider Tecovirimat and vaccinia immune globulin for people who are pregnant and are severely ill (Published 2 July 2022) 	<ul style="list-style-type: none"> • None identified
Treatment	<ul style="list-style-type: none"> • None identified 	<ul style="list-style-type: none"> • According to the U.S. CDC, there is currently no treatment available specifically for MPX infections, however there are medical countermeasures available through the Strategic National Stockpile (SNS) with limited available evidence on its effectiveness for the treatment of monkeypox such as: 1) Tecovirimat; 2) Vaccinia Immune Globulin Intravenous (VIGIV); 3) Cidofovir; and 4) Brincidofovir

Table 3: Key findings from highly relevant documents and experiences from the previous version of the LEP

Organizing framework domain	Evidence from previous version	Experiences from previous version
Biology	<ul style="list-style-type: none"> • A medium-quality systematic review and a non-systematic review reported that monkeypox is a zoonotic disease caused by the monkeypox virus which is a member of the orthopoxvirus genus (6/11 AMSTAR rating; literature last searched 15 August 2018; Published 12 November 2020) • A medium-quality systematic review and non-systematic review described that the monkeypox virus falls into two distinct strains, based on genetic, geographic, and phenotypic variation, these being the West African and the Congo Basin groups, with defined epidemiological and clinical differences (6/11 AMSTAR rating; literature last searched 15 August 2018; Published December 2019) 	<ul style="list-style-type: none"> • Countries and provinces examined characterize monkeypox as a viral zoonotic disease caused by an orthopoxvirus
Epidemiology (including transmission)	<ul style="list-style-type: none"> • A non-systematic review reported that monkeypox transmission in healthcare settings outside of endemic regions found that although many exposures in healthcare settings have been documented, only a single transmission event has been reported (Published 9 June 2022) • A non-systematic review conducted a pooled analysis of 124 cases in Italy, Australia, Czech Republic, Portugal, and the United Kingdom, and found that the current monkeypox epidemic differs from previous outbreaks in terms of age (54.29% of individuals in their 30s), gender (most cases being males), risk factors and transmission route, with sexual transmission being highly likely <ul style="list-style-type: none"> ○ Risk factors included being male, having sex with other men, human immunodeficiency virus positivity, and a history of previous sexually transmitted infections (Published 8 June 2022) • A single study (pre-print) reported on the incubation period for monkeypox in the Netherlands and found that the average incubation period was 8.5 days and can reach up to 17 days, which the authors concluded that these findings supports the use of 21 days for monitoring or quarantining close contacts to limit the spread of monkeypox infection (Published 13 June 2022) • A single study assessed the effect of an enhanced surveillance approach to detect monkeypox virus (MPX) cases in Nigeria, which involved community volunteers who were trained to conduct active case searches and follow-up in 	<ul style="list-style-type: none"> • The Public Health Agency of Canada reported a total of 168 cases of monkeypox in Canadian provinces and territories as of 17 June 2022, with 141 cases confirmed in Québec, 21 cases in Ontario, four cases in Alberta, and two cases in British Columbia • As of June 17 2022, the U.S. has reported a total of 113 confirmed monkeypox cases • As of 17 June 2022, the Public Health Agency has confirmed 607 cases of orthopoxvirus in Spain • Between 7 May 2022 and 16 June 2022, 574 cases of monkeypox have been confirmed in the UK • As of 21 June 2022, there are 469 confirmed cases of Monkeypox across 14 federal states in Germany • As of 21 June 2022, Portugal has reported 304 confirmed cases • In Portugal, the Directorate-General for Health suggested that transmission is occurring through close contact, including sexual intercourse • In France, 67 of the confirmed 277 Monkeypox cases reported a travel history to either Spain, Belgium, Germany, Portugal, United Kingdom, United States of America, Netherlands, Morocco, India, Switzerland,

	<p>addition to surveillance support, and found that this approach improved reporting of monkeypox in hotspots (Published 25 May 2022)</p> <ul style="list-style-type: none"> • A single study (pre-print) reported on a branching process transmission model and found that the basic reproduction number for monkeypox could be substantially larger than one among men who have sex with men (MSM) sexual contact network, and recommended that ongoing support and public health messaging should be implemented for prevention and early detection within the MSM network who have a large number of partners (Published 13 June 2022; Pre-print) • As of 2 June 2022, 780 laboratory confirmed cases have been notified to WHO under the International Health Regulations (IHR) or identified by WHO from official public sources in 27 non-endemic countries in four WHO regions (Published 4 June 2022) <ul style="list-style-type: none"> ○ Preliminary data from PCR assays indicate that the monkeypox virus strains detected in Europe and other non-endemic countries belong to the West African clade ○ Currently, the public-health risk at the global level is assessed as moderate, however the public-health risk could become high if the virus establishes itself in non-endemic countries as a widespread human pathogen • WHO provides the following interim advice: <ul style="list-style-type: none"> ○ All countries should be on the alert for signals related to people presenting with a rash that progresses in sequential stages that may be associated with fever, enlarged lymph nodes, back pain, and muscle ache ○ Increasing awareness among potentially affected communities, as well as healthcare providers and laboratory workers, is essential for identifying and preventing further cases and effective management of the current outbreak ○ Caring for patients with suspected or confirmed monkeypox requires early recognition through screening protocols adapted to local settings; prompt isolation and rapid implementation of appropriate infection, prevention and control measures; testing to confirm diagnosis; symptomatic management of patients with mild or uncomplicated monkeypox; and monitoring for and treatment of complications and life-threatening condition • A non-systematic review reported that monkeypox cases have been growing across an expanding number of non-endemic countries in recent months <ul style="list-style-type: none"> ○ Future outbreaks are likely to increase in size and frequency due to the cessation of smallpox vaccine programs, which provide cross-protection 	<p>Denmark, Greece, Luxembourg, Colombia, Cyprus, Serbia, or Mali</p> <ul style="list-style-type: none"> • The UK Health Security Agency has published a technical briefing investigating the monkeypox outbreak in England which addresses: <ul style="list-style-type: none"> ○ Assessed level of the outbreak in England ○ Research and evidence gaps prioritisation ○ Epidemiologic update, including findings from rapid sexual health questionnaires completed by cases ○ Genomic information ○ Transmission dynamics • Monkeypox cases have continued to spread in non-endemic countries in Europe, Australia, the United States and Canada • As of 7 June 2022, Canadian provinces and territories have publicly reported 81 cases of monkeypox, with 71 cases confirmed in Québec, eight cases in Ontario, and one case each in Alberta and British Columbia • As of 6 June 2022, 30 cases of monkeypox have been reported in the U.S. However, additional cases are under investigation and other suspected cases without confirmation have been identified • Canada's Chief Public Health Officer, Dr. Theresa Tam reported at a news conference on 3 June 2022 that a disproportionate number of the confirmed cases in Canada are among gay and bisexual men, but warned that anyone can be potentially susceptible to the disease <ul style="list-style-type: none"> ○ Dr. Tam encouraged public-health officials to learn from the experience of the HIV/AIDS epidemic and to involve communities that have the most impacts right from the start. • In Europe, cases have continued to spread, with more than 300 cases now confirmed in the U.K., 198 cases in Spain, 166 in Portugal, 80 in Germany, 66 in France, and outbreaks or cases identified in several other European countries • To date, transmission within and across countries appears to be circulating below the detection of
--	---	--

	<ul style="list-style-type: none"> ○ Based on global travel trends, traveller volumes originating from flights from countries where monkeypox is endemic are greatest to Paris, London, Dubai, Johannesburg, and Brussels ○ Supporting endemic countries by strengthening laboratory capacity and increasing timely access to smallpox vaccination for close contacts can help mitigate further chains of transmission (Published 31 May 2022) ● A non-systematic review by the European Centre for Disease Prevention and Control (ECDC) reported MPX cases across nine countries (Austria, Belgium, France, Germany, Italy, Portugal, Spain, Sweden, and the Netherlands) <ul style="list-style-type: none"> ○ Countries should update their contact-tracing mechanisms and review availability of smallpox vaccines, personal protective equipment, and antivirals ○ Healthcare workers should wear gloves, water-resistant gowns, and FFP2 respirator when screening suspected cases or caring for monkeypox cases ○ Proactive risk communication and multiple community-engagement activities should be implemented to provide updates and increase awareness for those at risk and the wider public (Published 23 May 2022) ● A single study reported two cases of monkeypox within two white British men <ul style="list-style-type: none"> ○ The study indicated that skin lesions at the point of sexual contact were likely the primary location of infection, which was followed lymphadenopathy, fever, headache, and diarrhea ● The authors concluded that healthcare workers should use appropriate PPE and receive education on clinical pathways to manage possible monkeypox cases, and encouraged collaborative efforts with clinicians and patients to ensure sensitive community engagement/education to avoid stigmatization ● A medium-quality systematic review reported that outside of the Democratic Republic of Congo (DRC), there has been a notable increase in number of individual monkeypox outbreak reports between 2010 and 2018, particularly in the Central African Republic, but the authors noted that this does not necessarily translate to an increase in annual cases over time in these areas <ul style="list-style-type: none"> ○ In Nigeria, geographical patterns of infections suggest a possible new and widespread zoonotic reservoir (6/11 AMSTAR rating; literature last searched 15 August 2018) ● A single study pre-print conducted in the Democratic Republic of Congo found that 70% of cases reported a generalized skin eruption within three 	<p>surveillance systems. In the U.K., contact-tracing investigations have linked transmission to gay bars, saunas, and the use of dating applications in the U.K. and abroad, but no single factor or exposure linking all cases has been identified</p> <ul style="list-style-type: none"> ● A case identified in Belgium, which as of 6 June 2022 has reported a total of 17 monkeypox cases, was linked to the monkeypox outbreak in Portugal ● In France, 28 of the confirmed 66 Monkeypox cases reported a travel history to Spain, Belgium, Germany, Portugal, the U.K., the U.S., Netherlands, Morocco, India, Switzerland, and Mali ● Human monkeypox was first identified in the Democratic Republic of the Congo in 1970 and has since been reported across several other central and western African countries and occasionally in countries outside of Africa including in the United States (47 cases in 2003 and one in 2021), the United Kingdom (four cases in 2018-19 and three in 2021), Israel (one case in 2018), and Singapore (one case in 2019). As of Wednesday 25 May 2022, there were 219 confirmed cases outside of countries in which monkeypox is endemic ● While cases have been confirmed in several countries in Europe and North America, 51 of these confirmed cases were reported in Madrid, Spain and 78 cases of monkeypox were confirmed in the U.K. between 7-24 May 2022. As of 25 May 2022, 16 cases have been confirmed in Canada ● Monkeypox can spread to humans via animals (rodents and primates) as well as other humans and contaminated objects such as bedding. Animal-to-human transmission may occur by bite or scratch, bushmeat preparation, direct contact with body fluids or lesion material, or indirect contact with lesion material, such as through contaminated bedding
--	--	--

	<p>weeks of contact with a person infected with monkeypox (Last updated 5 June 2022; Pre-print)</p> <ul style="list-style-type: none"> • A low-quality systematic review reported that from 2009-2019 there have been almost 20,000 suspected or confirmed cases of monkeypox and of those cases, one case was in Israel in 2018, three in the UK in 2018 and one in 2019, and one in Singapore in 2019 <ul style="list-style-type: none"> ○ The median age at presentation has increased from four to five years old from 1970-1989 to 21 years in 2010-2019, with cases outside of Africa even higher and occurring most frequently in adult males ○ The authors hypothesize that this increase may be due to the cessation of smallpox vaccinations, which provided some cross-protection against monkeypox (4/11 AMSTAR rating; literature last searched 7 September 2020) • A non-systematic review reported that the two possible means of monkeypox virus transmission are animals-human transmission and human-human transmission, and respiratory droplets and contact with body fluids, contaminated patient's environment or items, skin lesion of an infected person associated with inter-human transmission (Published 12 November 2020) <ul style="list-style-type: none"> ○ Animal-to-human transmission occurs through direct contact with the above viral hosts or by direct contact with blood ○ Human-to-animal transmission has not been reported • A non-systematic review reported that the frequency and geographic distribution of human monkeypox cases across West and Central Africa have increased in recent years <ul style="list-style-type: none"> ○ Monkeypox is largely found in rodents and has been detected in squirrels, rats, mice, and monkeys ○ Indirect or direct contact with live or dead animals is assumed to be the main source of human monkeypox infections ○ Secondary human-to-human transmission is considered common and presumably occurs through respiratory droplets or indirect or direct contact with body fluids, lesion material and contaminated surfaces or other material (Published December 2019) • A non-systematic review indicated that transmission to humans is primarily by exposure to animal reservoirs (primary zoonotic transmission), such as squirrels (Published April 2019) • A non-systematic review reported that the current evidence indicates that an outbreak is caused by multiple sources emerging into the human population, 	<ul style="list-style-type: none"> • Human-to-human transmission is thought to generally occur through large respiratory droplets requiring prolonged face-to-face contact • An infected pregnant women may also pass monkeypox on to their developing fetus
--	---	--

	<p>and is not sustained by human-to-human transmission; however, most cases are reported individually which prevents an accurate picture of the overall transmission</p> <ul style="list-style-type: none">○ There are current knowledge gaps in the epidemiology, host reservoir, emergence, transmission, pathogenesis, and prevention of monkeypox● A single study described an imported case of monkeypox from Nigeria to the United Kingdom, whereby secondary transmission occurred within the family<ul style="list-style-type: none">○ After arrival, case one developed a vesicular lesion, day 19 an 18-month old child within the family developed lesions, and by day 33, an adult member developed a vesicular rash and confirmed with monkeypox through PCR testing○ 30 contacts were identified for active surveillance as they had direct exposure of broken skin or mucous membrane to a symptomatic patient (Published 21 August 2021)● A single study found that in the Democratic Republic of the Congo, the incidence of monkeypox from 2011-2015 was lower among those presumed to have received smallpox vaccination than among those presumed unvaccinated<ul style="list-style-type: none">○ The highest incidence was among 10-19-year-old males, the cohort reporting the highest proportion of animal exposures (37.5%)○ The authors concluded that the increase in the incidence of monkeypox might be linked to declining immunity provided by smallpox vaccination (Published 4 June 2021)● A single study used historical data from the Democratic Republic of the Congo to estimate the reproduction number (R) and basic reproduction number (R0) of smallpox and monkeypox in a population with imperfect immunity<ul style="list-style-type: none">○ With data from 2011-2012 that indicate a 60% population immunity against orthopoxvirus species, the R value for monkeypox was calculated to be 0.85 (UI: 0.51-1.25) (Published 8 July 2020)● A single study described the transmission of monkeypox virus from an investigation that Public Health England (PHE) conducted of two unrelated cases of monkeypox that affected travelers returning from Nigeria<ul style="list-style-type: none">○ Transmission of monkeypox occurred between the second patient to a healthcare worker, most likely the only exposure risk identified during assessment of the infected healthcare worker was the changing of potentially contaminated bedding, when patient 2 had multiple skin lesions	
--	--	--

but before a diagnosis of monkeypox had been considered (Published April 2020)

- A [single study](#) examined the association between exposure to rodents and non-human primates with rash severity amongst confirmed cases from the monkeypox surveillance program in the Democratic Republic of the Congo
 - The authors reported no association found between rodent exposure and monkeypox rash severity (Published 24 December 2019)
- A [single study](#) described the the seroprevalence of orthopoxviruses amongst employees of a primate sanctuary and residents of nearby villages in Cameroon
 - Forty-three participants (34.4%) were IgG positive for anti-orthopoxvirus antibodies; however, amongst those born after the era of routine smallpox vaccination only four (6.3%) were positive for anti-orthopoxvirus antibodies
 - The authors concluded that presence of anti-orthopoxvirus antibodies in individuals born after the era of smallpox vaccination suggests the possibility of asymptomatic circulation of an orthopoxvirus (which was most likely monkeypox) in human populations (Published 25 November 2019)
- A [single study](#) reported the epidemiological features of the 2017 to 2018 human monkeypox outbreak in Nigeria, the largest documented human outbreak of the west African strain of the monkeypox virus
 - Data was collected with a standardized form based on a case definition of human monkeypox from previously established guidelines
 - Diagnosis of the human monkeypox virus infection was confirmed by viral identification with real-time PCR and detection of antibodies
 - The results showed that 122 confirmed or probable cases of human monkeypox was recorded in 17 states of Nigeria, infecting individuals from the ages of two to 50 years
 - All patients had rashes on all parts of the body, fever, headaches, and lymphadenopathy
 - The results suggest endemicity of monkeypox virus in Nigeria, with some evidence of human-to-human transmission (Published August 2019)
- A [single study](#) reported an outbreak investigation involving human monkeypox cases from four districts (Impfondo, Betou, Dongou, and Enyelle) in the Likouala department of the Republic of the Congo
 - The results showed that there were no epidemiologic links between cases from different districts, and all hypothesized human to human

	<p>transmission events appeared to have been contained within the individual districts</p> <ul style="list-style-type: none"> ○ There was no evidence suggesting that the virus was introduced from neighbouring countries ○ The authors noted some challenges associated with the remote regions of the districts, such as limited health and transportation infrastructure, absence of specimen collection supplies, and a well-functioning cold chain, that would have resulted in inconsistent and incomplete reporting (Published February 2019) ● A single study found that rope squirrels shed large quantities of the virus and for long periods, supporting the hypothesis that they play a potential role in monkeypox virus transmission to humans and other animals in the Central African region (Published 21 August 2017) 	
Prevention and control	<ul style="list-style-type: none"> ● The WHO released interim guidance on vaccines and immunization for monkeypox <ul style="list-style-type: none"> ○ The organization does not recommend the use of first-generation vaccines held in national reserves related to the smallpox eradication program ○ Mass vaccination is not required or recommended at this time based on current assessment of risks and benefits, but strongly encouraged to countries to convene their national immunization advisory groups to determine relevance and context ○ Most interim vaccination recommendations are related to off-label use (i.e., smallpox vaccines off-label for monkeypox) and vaccines approved for monkeypox such as MVA-BN, LC16, or ACAM2000 ○ Pre-exposure prophylaxis (PrEP) is recommended for health workers at high risk, laboratory personnel working with orthopoxviruses, clinical laboratory personnel performing diagnostic testing for monkeypox, and any outbreak response team members ○ Vaccination program should be accompanied with strong communication and conduct of vaccine effectiveness studies (Published 14 June 2022) ● A single study described the development and implementation of a mobile response survey for notification of possible exposure, risk assessment and stratification, and symptom monitoring for healthcare personnel after exposure to the monkeypox virus at Massachusetts General Hospital <ul style="list-style-type: none"> ○ These tools were deployed within 24 hours of identification of a patient with suspected MPX, with the full suite in production within 4 days of confirmation of the diagnosis of MPX (Published 16 June 2022; Pre-print) 	<ul style="list-style-type: none"> ● An Emergency Committee of the World Health Organization will convene on June 23 to determine if orthopoxvirus is an international threat ● In Canada, on 8 June 2022, the National Advisory Committee on Immunization (NACI) released interim guidance on the use of Imvamune, a third-generation smallpox vaccine, for post-exposure prophylaxis (PEP) against monkeypox: <ul style="list-style-type: none"> ○ A single dose of Imvamune may be offered to individuals with high-risk exposures of a probable or confirmed case of monkeypox, or in setting where transmission is occurring, ideally within four days of exposure ○ PEP should not be offered to individuals who already have a monkeypox infection ○ A second dose of Imvamune may be offered after 28 days of the first dose if continued risk of exposure is indicated ● NACI also recommended Imvamune pre-exposure prophylaxis (PrEP) for adults at high risk of occupational exposure in a laboratory research setting and for special populations, such as individuals who are immunocompromised, pregnant, lactating, children and youth who are less than 18 years old, and individuals with atopic dermatitis based on exposure risk

<ul style="list-style-type: none"> ● The WHO developed the following interim guidance on risk communication and community engagement (Published 2 June 2022): <ul style="list-style-type: none"> ○ “Identify target groups relevant to the monkeypox outbreak in Europe (i.e., population groups at risk need to be alerted about specific risks and protective measures; broader public needs to be informed about disease and preventive measures) ○ Tailor risk communication through channels and spokespersons that target groups trust ○ Acknowledge uncertainty by labelling public-health advice as preliminary and based on current evidence, and committing to provide further information and guidance as it becomes known ○ Package messages and health advice relevant to specific settings and circumstances ○ Provide public-health advice specific to the monkeypox outbreak without comparing it with or leveraging other health issues ○ Use pictures of monkeypox symptoms to increase understanding but not generate fear ○ Community-engagement approaches should be used to support targeted risk communication messages to populations or groups more likely to be exposed to the virus, which would require that public-health authorities at national and sub-national level identify and actively work with relevant civil society organizations, community-based organizations and stakeholders, and leverage the trust they have to ensure that the affected communities are properly informed and empowered to protect themselves from the disease” ● The WHO released guidance on surveillance, case investigation, and contact tracing (Published 22 May 2022) <ul style="list-style-type: none"> ○ If there is a suspect case of monkeypox virus, case investigation should consist of clinical examination of the patient with appropriate personal protective equipment (PPE), questioning the patient about possible sources of infection, and safe collection and dispatch of specimens for laboratory examination to be confirmed for monkeypox ○ As soon as a suspected case is identified, contact identification and contact tracing should be initiated, and contacts should be monitored at least daily for the onset of any signs or symptoms for a period of 21 days from last contact with a patient or contaminated materials ○ Quarantine or exclusion from work are not necessary during the contact-tracing period if there are no symptoms present or begin to develop 	<ul style="list-style-type: none"> ● In Germany, The Standing Committee on Vaccination (STIKO) has put forth a recommendation to vaccinate individuals against the Monkeypox virus with Imvanex <ul style="list-style-type: none"> ○ This includes vaccinations for certain population groups, including 1) post-exposure prophylaxis upon Monkeypox exposure in asymptomatic individuals aged 18 years and older (e.g., those who have had close physical contact with individuals with Monkeypox); 2) individuals with an increased risk of exposure and infection during a potential outbreak (e.g., men aged 18 years and older with same-sex sexual contacts or multiple partners); and 3) immunocompromised individuals ○ For those who have not previously been vaccinated against smallpox, immunization with Imvanex is a two-dose regimen separated 28 days apart, while a single dose is sufficient for those with a previous smallpox vaccine (barring immunocompromised individuals who would still receive two doses in either case) ● The Public Health Agency of Canada has issued a travel health notice, last updated 20 June 2022, to practise enhanced health precautions when traveling to certain countries <ul style="list-style-type: none"> ○ Enhanced health precautions may include using personal protective equipment, delaying travel until risk is lower, avoiding higher risk activities, and additional vaccinations for certain groups ○ Talking to sexual partners about sexual health and using barriers such as gloves and condoms ○ Avoid sharing toothbrushes, sex toys, and drug use supplies ○ Avoid prolonged face-to-face contact, especially indoors ○ Stay home if you are sick, and encourage others to do the same
--	---

- | | |
|---|--|
| <ul style="list-style-type: none"> • The authors of a single study pre-print conducted in the Democratic Republic of Congo recommended that rapid field diagnostics should be implemented for early detection and surveillance (Last updated 5 June 2022; Pre-print) • A non-systematic review noted that vaccination against smallpox provides cross-protection against other OPV species including monkeypox and many patients were born after the cessation of smallpox eradication program (Published 12 November 2020) • A separate non-systematic review similarly highlighted that most confirmed monkeypox cases are younger than 40-years old, a population born only after the discontinuation of the smallpox vaccination campaign, possibly reflecting a lack of cross-protective immunity (Published December 2019) <ul style="list-style-type: none"> ○ Prevention measures for animal-to-human transmission include avoiding contact with rodents and primates, limiting direct exposure to blood and inadequately cooked meat, and using personal protective equipment when handling potential animal reservoir species ○ Prevention measures for human-to-human transmission include avoiding close contact with anyone infected and healthcare providers using personal protective equipment when treating infected patients • A non-systematic review highlighted that other key public health measures, such as case isolation, contact tracing, avoiding contact with animals or materials suspected of being infected, use of personal protective equipment and good hand-hygiene practices, remain the best measures for preventing and controlling human monkeypox (Published April 2019) • A single study of an outbreak of monkeypox mentions the use of contact tracing and active surveillance of 30 contacts identified as having had direct exposure of broken skin or mucous membranes to a symptomatic patient (Published 21 August 2021) • A cross-sectional single study of strategies used, and challenges faced when responding to a monkeypox outbreak noted (Published 17 April 2019): <ul style="list-style-type: none"> ○ To respond to the outbreak, the hospital established a make-shift isolation ward for case management by a monkeypox response team and provided infection and control resources ○ Challenges included some healthcare workers being reluctant to participate in the outbreak with some avoiding suspected patients; stigma and discrimination experienced by patients and their family members; and refusal of isolation and | <ul style="list-style-type: none"> • Asymptomatic patients can be managed in a primary care setting, vaccination clinics and other outpatient settings such as sexual health clinics • A report by Public Health Ontario dated 13 June 2022 indicated that self-isolation must be maintained until all scabs have fallen off, new skin is present, and they have been cleared by their public health unit (no longer considered infectious) <ul style="list-style-type: none"> ○ An AIIR is not required for specimen collection ○ It is recommended that hand hygiene facilities be available in laundry areas, and that clothes from monkeypox cases be machine washed using 70-degree Celsius hot water and regular laundry detergent ○ Routine environmental disinfection must occur in emergency rooms and outpatient settings, inpatient rooms, and shared showering facilities • A technical report by Public Health Ontario dated 28 May 2022 describes interim case and contact management guidelines for local public health units based on information from selected public health organization such as the CDC, the United Kingdom Health Security Agency, and the WHO <ul style="list-style-type: none"> ○ For those self-isolating, it is recommended to cover skin lesions by wearing long clothing, designating one person to care for the person who is self-isolating ○ It is recommended to wear gloves when handling laundry, to not shake or agitate soiled laundry dispersing infectious particles ○ Contaminated dressings and bandages should not be disposed of with household garbage or in landfills, so consider using a biohazard/environmental remediation company to transport waste safely to the hospital for safe processing ○ A detailed guide to assessing risk of exposure is provided in the document • The UK passed legislation to make monkeypox a notifiable disease in law as of 8 June 2022 |
|---|--|

	<ul style="list-style-type: none"> ○ Training was offered and using a collaborative approach among all involved stakeholders addressed some of these challenges and eventually led to successful containment of the outbreak ● A single study examining thresholds to trigger a public-health response to monkeypox identified three different statistical thresholds that were used: Cullen, c-sum, and a World Health Organization (WHO) method based on monthly incidence (20 December 2018) <ul style="list-style-type: none"> ○ The study concluded that using signals detected by a single method may be inefficient and overly simplistic for triggering public-action for monkeypox ● Instead, a response algorithm is proposed which integrates the WHO method as an objective threshold with contextual information about epidemiological and spatiotemporal links between suspected cases 	<ul style="list-style-type: none"> ○ This legislation means that doctors are required to notify their local council or Health Protection Team if they suspect a patient has monkeypox and laboratories must notify the UK Health Security Agency if they identify monkeypox virus in a sample ○ To ensure anyone concerned about monkeypox seeks appropriate healthcare, the National Health Service regulations were amended to make monkeypox treatment and diagnosis free from charge for all overseas visitors ● The government of Australia has convened national expert groups to develop treatment and vaccine guidelines ● The Italian Ministry of Health issued a variety of recommendations: case notification, protective measures for healthcare workers, contact tracing, possibly implementing quarantine measures, as well as providing non-stigmatizing information to at-risk populations ● In Portugal, The Directorate-General for Health disseminated communication materials related to transmission, prevention, and hygiene measures to reduce the risk of monkeypox ● Dissemination activities include raising awareness at public and private events ● The UK Health Security Agency has produced guidance regarding the cleaning of sex-on-premises venues in light of the monkeypox virus outbreak ● The UK Health Security Agency has produced guidance regarding home isolation for people who have been diagnosed with monkeypox infection ● Cases are being asked to isolate at home, if they are well enough, and to avoid contact with others until lesions have healed and scabs have dried ● In some jurisdictions, new recommendations and guidelines have been put in place to help prevent and control the spread of monkeypox
--	---	--

		<ul style="list-style-type: none">○ For example, the UK Health Security Agency alongside the public-health agencies of England, Scotland, Wales and Northern Ireland have released a consensus statement regarding principles for monkeypox control in the U.K. to guide the public-health response to ensure there is a proportionate response that encourages engagement with health services, prevents stigma, and controls spread○ As part of these guidelines, the smallpox vaccine is being offered to health workers who will care for monkeypox patients as well as those who work in sexual-health centres and may have assessed suspected cases○ In Germany, RKI released a recommendation on 30 May 2022 about hygiene measures for the treatment and care of patients diagnosed with Monkeypox in healthcare facilities, which includes the use of hand disinfectant, disposable medical gloves, personal protective equipment, and providing spatial accommodation (i.e., single rooms for infected patients)○ The country has also planned for an additional 200,000 smallpox vaccine doses to follow the original order of 40,000 smallpox vaccine doses○ In France, a recommendation was released on 24 May 2022 to launch a targeted vaccination strategy to help reduce the transmission of the monkeypox virus○ The recommendation includes providing smallpox vaccinations for at-risk adults (e.g., exposed healthcare professionals) who have been in contact with infected individuals○ Vaccinations should occur within the first two weeks of exposure (ideally within the first four days) and using a two-dose regimen given 28 days apart○ Immunocompromised individuals should receive three doses
--	--	--

		<ul style="list-style-type: none">• Several jurisdictions have also noted efforts to manage community engagement and provide targeted communication about the monkeypox virus<ul style="list-style-type: none">○ In Spain and Portugal, public-health authorities are engaging with LGBTQI+ communities○ Further, the UK Health Security Agency is working with partners to communicate with sexual-health service partners as well as the gay, bisexual, or other men who have sex with men community about monkeypox and how to stay safe• Broadly, jurisdictions align with the recommendations from the U.S. CDC, which recommends that the following measures be taken to prevent infection with monkeypox virus:<ul style="list-style-type: none">○ Avoid contact with animals that could harbour the virus (including animals that are sick or that have been found dead in areas where monkeypox occurs);○ Avoid contact with any materials, such as bedding, that has been in contact with a sick animal;○ isolate infected patients from others who could be at risk for infection;○ Practice good hand hygiene after contact with infected animals or humans (e.g., washing your hands with soap and water or using an alcohol-based hand sanitizer); and○ Use personal protective equipment (PPE) when caring for patients• The countries reviewed also noted that high-risk contacts such as sexual partners, family members, and others in contact with skin blisters should also quarantine<ul style="list-style-type: none">○ If they take a test that has a negative result, they may end their quarantine and if the result is positive, they should continue isolating. Across jurisdictions, recommended isolation periods include periods of at least 21 days or others that recommend until the scabs have fallen off and their skin is completely healed
--	--	--

		<ul style="list-style-type: none"> ○ Belgium was the first country to announce a mandatory 21-day isolation period for individuals infected with monkeypox ● Many jurisdictions have source and contact-tracing measures in place in the event of a confirmed case <ul style="list-style-type: none"> ○ The UK Health Security Agency produced a monkeypox contact tracing classification and vaccination matrix to help guide follow-up and vaccination advice for individuals who have had varying levels of exposure risk with confirmed cases of monkeypox ○ The Ontario Monkeypox Investigation Tool was created to record patient information and prevent future illness caused by monkeypox. ○ Germany ordered 40,000 smallpox vaccine doses as a preventive measure and the U.K. has purchased supplies of Imvanex (a smallpox vaccine) to be offered to close contacts of those diagnosed with monkeypox to reduce their risk of symptomatic infection and severe illness
Clinical presentation	<ul style="list-style-type: none"> ● A high-quality systematic review (pre-print) appraised 14 guidelines focusing on the availability, scope, quality, and inclusivity of clinical managements for monkeypox virus globally, and found that most of the guidelines were of low-quality due to a lack of detail in its methodology and narrow range of covered topics <ul style="list-style-type: none"> ○ Most guidelines focused on adults, with some providing advice for children, pregnant women, and immunocompromised individuals ○ Treatment guidance was mostly limited to advice on antivirals, in which seven out of 14 guidelines advised cidofovir ○ All guidelines recommended vaccination as post-exposure prophylaxis (PEP) (Published 14 June 2022; AMSTAR rating 7/9) ● A non-systematic review conducted a pooled analysis of 124 cases in Italy, Australia, Czech Republic, Portugal, and the United Kingdom, and found that clinical presentation is also atypical, being largely characterized by anogenital lesions and rashes, with fewer on the face and extremities <ul style="list-style-type: none"> ○ The most common symptom reported was fever (54.29%) followed by inguinal lymphadenopathy (45.71%) and exanthema (40%) (Published 8 June 2022) 	<ul style="list-style-type: none"> ● In Italy, a letter to the editor dated 9 June 2022 reported a total of 29 PCR-confirmed cases <ul style="list-style-type: none"> ○ 28/29 cases were males, and 16/18 reported having sex with other men ○ The median age of patients was 36 years ○ All presented with a rash, and in 18/21 cases, the rash was localized in the genital/perianal area ○ Fever was reported in 12/22 cases for whom information was available ● In the Netherlands, as of 31 May 2022, all 31 cases were men and identified as MSM with an age range of 23-64 years <ul style="list-style-type: none"> ○ 18 cases had reported symptom onset and the most likely date of exposure related to attending an event ○ The 97.5 percentile for the incubation period is estimated to be 19.9 days, and an estimated 2% of all cases would develop symptoms more than 21 days after being exposed

<ul style="list-style-type: none"> • A single study reported on two cases with exclusive genital lesions, which the authors concluded that this may suggest monkeypox virus can be sexually transmitted, and recommended increased awareness among clinicians and ring vaccination (Published 14 June 2022) • A retrospective observational study examined the longitudinal clinical course of monkeypox in the U.K., viral dynamics, and the adverse events of novel antiviral therapies in seven patients who were diagnosed from 2018-2021 (Published 24 May 2022) <ul style="list-style-type: none"> ○ Viraemia, prolonged virus DNA detection in upper respiratory tract swabs, low mood, and PCR-positive deep tissue abscess were some of the disease features • A pre-print of a prospective observational study conducted in the Democratic Republic of Congo reported the findings from 216 patients with monkeypox <ul style="list-style-type: none"> ○ Fetal death was reported among four of five patients who were pregnant ○ Patients who died had higher viral DNA and the maximum lesion count ○ The most common complaints were rash (96.8%), malaise (85.2%), sore throat (78.2%), and lymphadenopathy/adenopathy (57.4%) • Patients under five years of age had the highest lesion count, and primary household cases tended to have higher lesion counts than secondary household cases (Last updated 29 May 2022; Pre-print) • A non-systematic review reported that monkeypox symptoms can occur in three phases including: 1) an incubation period of four to 21 days; 2) prodromal illness with signs including lymph node enlargement, headache, fever, back pain, myalgia, intense asthenia, pharyngitis, sweating and malaise; and 3) followed by an exanthema phase that includes vesiculopustular rashes that appear within one to 10 days spread over the body) (Published 12 November 2020) • A non-systematic review described that monkeypox is similar to smallpox but generally less severe (Published December 2019) <ul style="list-style-type: none"> ○ Incubation period is estimated at five to 21 days, and symptoms and signs at two to five weeks ○ The illness begins with nonspecific symptoms and signs including fever, chills, headaches, lethargy, asthenia, lymph node swelling, back pain, and myalgia, followed by rashes of varying size that appear first on the face then across the body, hands, legs, and feet 	<ul style="list-style-type: none"> • The literature indicates that incubation periods differ by route of transmission (non-invasive exposure through skin or droplets is 13 days, and complex and invasive exposure through contact with broken skin or mucous membranes is 9 days), which is consistent with smallpox • A recent Eurosurveillance case report described a case of monkeypox infection in an individual returning to Australia from Europe, with the individual reporting a genital rash, followed by a fever and lymphadenopathy, which then led to diffuse rash with few lesions present on the face and extremities • The incubation period can range from five to 21 days • At the onset of the infection, symptoms are described as mild and include fever, headache, muscle ache, swollen lymph nodes, chills, and fatigue • Between one and five days after the onset of fever, a rash develops, often starting on the face and then spreading to other parts of the body with the rash tending to be more concentrated on the face and extremities than on the trunk <ul style="list-style-type: none"> ○ Generally, the disease affects the face (in 95% of cases); the palms of the hands and soles of the feet (in 75% of cases); the oral mucosa (in 70% of cases); the genitalia (30%); and the conjunctiva and cornea (20%) ○ However, in most of the known recent cases in Europe, the rash has started around the pubic or anus region before spreading to the rest of the body • The B.C. Centre for Disease Control maintains a webpage about monkeypox for healthcare providers with information about clinical presentation, transmission, management of suspected cases (including diagnosis and testing), infection prevention and control, and treatment
---	--

	<ul style="list-style-type: none"> ○ Complications such as secondary bacterial infections, respiratory distress, broncho-pneumonia, encephalitis, corneal infection with vision loss, gastrointestinal involvement, vomiting, and diarrhea with dehydration ○ Case fatality rates have varied between 1% and 10% and occur mostly among young adults and children, especially those with immunosuppression ● A non-systematic review indicated that the clinical presentation of the monkeypox virus largely resembles that of smallpox, with an incubation period of seven to 17 days, and includes fever, muscle aches, backache, lymphadenopathy, followed by lesions and rashes all over the body (Published April 2019) ● A non-systematic review indicated that the clinical presentations of the monkeypox virus includes symptoms with skin and mucosal lesions which are difficult to distinguish from smallpox, and the infection starts with fever, headache, back pain, myalgia and asthenia followed by eruption of skin and mucosal lesions starting with the face (Published January 2019) ● A single study reported that a suspected monkeypox case was defined as an individual with a vesicular or pustular rash with deep-seated, firm pustules, and ≥ 1 of the following symptoms: fever preceding the eruption, lymphadenopathy (inguinal, axillary, or cervical), or pustules or crusts on the palms of the hands or soles of the feet (Published 4 June 2021) ● A single study described the clinical course and management of 40 hospitalized monkeypox cases during the 2017-2018 human monkeypox outbreak in Nigeria using retrospective records <ul style="list-style-type: none"> ○ The most common clinical features observed (in order) included skin rash, fever, lymphadenopathy, genital ulcers, body aches, headache, sore throat, pruritus, and conjunctivitis and photophobia ○ The most common first symptoms were rash and fever ○ Twenty-one (52.5%) of 40 cases developed one or more complications including (in order of frequency) secondary bacterial infection, gastroenteritis, sepsis, bronchopneumonia, encephalitis, keratitis, and premature rupture of membrane at 16 weeks' gestation and resultant intrauterine fetal death ○ Patients with HIV type 1 coinfection were significantly more likely to have larger skin rashes, genital ulcers, secondary bacterial infection, and longer duration of illness ○ Sequelae observed amongst 18 patients discharged from hospital and seen at follow-up included hyperpigmented atrophic scars, hypopigmented 	
--	---	--

	atrophic scars, patchy alopecia, hypertrophic skin scarring, and contracture/deformity of facial muscles; three of the 18 patients showed complete healing after eight weeks of follow-up (Published 15 October 2020)	
Diagnosis	<ul style="list-style-type: none"> • A non-systematic review highlighted that of monkeypox can occur through genetic methods (i.e., PCR or RT-PCR), phenotypic methods based on clinical diagnosis, immunological methods including IgG and IgM antibody detection and immunohistochemistry for viral antigen detection, and electron microscopy (Published 12 November 2020) <ul style="list-style-type: none"> ○ For diagnosis, optimal clinical specimens for laboratory analyses include those from skin lesions, exudate, or crusts stored in a dry, sterile tube (without viral transport media) and kept cold • A single study noted that that a confirmed monkeypox case requires detection of Orthopoxvirus or monkeypox virus DNA with real-time polymerase chain reaction (PCR) or isolation of monkeypox virus in culture from ≥ 1 specimen (Published 4 June 2021) <ul style="list-style-type: none"> ○ swab eluates, crust homogenates, or blood from suspected cases were used to test monkeypox infection 	<ul style="list-style-type: none"> • In Italy, the rapid communications report dated 26 May 2022, noted four patients were positive for monkeypox DNA in real-time PCR using samples from skin, genital and anal lesions, serum, plasma, seminal fluid, feces, and the nasopharynx <ul style="list-style-type: none"> ○ Viral DNA was extracted by Qiamp Viral RNA mini kit (Qiagen) and two real-time PCRs using a Real-Star Orthopoxvirus PCR kit, and a G2R_G assay which was used as a confirmatory PCR ○ Sanger sequencing was used to identify which of the two clades the virus belonged to • Diagnosis of the monkeypox virus primary occurs first through clinical assessment and then confirmed through laboratory testing of biological specimens • Clinicians can recognize potential monkeypox infection based on the similarity of its clinical course to that of smallpox • The main feature that distinguishes infection with monkeypox from that of smallpox is the development of swollen lymph nodes (lymphadenopathy) • The spectrum of monkeypox disease ranges from mild to severe and fatal • The virus can be detected using polymerase chain reaction (PCR) and the particles can further be detected through an electron microscope. The UK Health Security Agency has produced guidance for collecting, submitting, and processing of samples for the diagnosis of monkeypox
Prognosis	<ul style="list-style-type: none"> • A single study of 40 monkeypox cases found that 21 (52.5%) developed one or more complications including (in order of frequency) secondary bacterial infection, gastroenteritis, sepsis, bronchopneumonia, encephalitis, keratitis, and premature rupture of membrane at 16 weeks' gestation and resultant intrauterine fetal death (published 15 October 2020) 	<ul style="list-style-type: none"> • The Eurosurveillance case report describing the monkeypox infection in an individual returning to Australia from Europe concluded that normal CD4+ T-cell count and suppressed HIV viral load on

	<ul style="list-style-type: none"> ○ Five (12.5%) of the cases died ○ Patients with HIV type 1 coinfection were significantly more likely to have larger skin rashes, genital ulcers, secondary bacterial infection, and longer duration of illness ○ Sequelae observed amongst 18 patients discharged from hospital and seen at follow-up included hyperpigmented atrophic scars, hypopigmented atrophic scars, patchy alopecia, hypertrophic skin scarring, and contracture/deformity of facial muscles; three of the 18 patients showed complete healing after eight weeks of follow-up ● A cross-sectional single study of 223 participants found that hunting of non-human primates was associated with rash severity in both unadjusted and adjusted models (OR= 2.78 (95% CI: 1.18, 6.58)), while exposure to non-human primates was associated with rash severity only in an unadjusted model (published 24 December 2019) <ul style="list-style-type: none"> ○ There was no association found between rodent exposure and monkeypox rash severity ● In an observational single study of fetal outcomes of four pregnant women with infected with monkeypox, three of four experienced fetal demise (17 October 2017) <ul style="list-style-type: none"> ○ The study concluded that maternal monkeypox infection may have adverse consequences for the fetus without apparent correlation with severity of maternal disease 	<p>antiretroviral therapy were potential important factors in preventing more severe outcomes</p> <ul style="list-style-type: none"> ● Most monkeypox cases are mild and the infected person will recover within a few weeks ● Although monkeypox is generally mild, it has been reported to be potentially more severe in children and immunocompromised individuals, as there is the possibility of superinfections of skin lesions or further complications arising from existing respiratory, digestive, ophthalmological, or neurological disorders ● Complications may include secondary bacterial infections, bronchopneumonia, sepsis, encephalitis, and corneal infection with subsequent loss of vision ● The severity of illness can depend upon the initial health of the individual, the route of exposure, and the strain of the infecting virus (West African vs. Central African virus genetic groups, or clades)
Treatment	<ul style="list-style-type: none"> ● A retrospective single study examined the longitudinal clinical course of monkeypox in the U.K., viral dynamics, and the adverse events of novel antiviral therapies in seven patients who were diagnosed from 2018-2021 <ul style="list-style-type: none"> ○ five patients remained in isolation for more than three weeks due to PCR positivity ○ three patients were treated with Brincidofovir (200 mg once a week orally), all developing elevated liver enzymes, which resulted in the stopping of therapy ○ one patient received Tecovirimat (600 mg twice daily for two weeks orally) and experienced no adverse effects with a shorter duration of viral shedding and illness (10 days of hospitalization) (Published 24 May 2022) ● A non-systematic review noted that monkeypox is primarily treated through supportive care, symptomatic management, and treatment of secondary bacterial infections (Published December 2019) ● A non-systematic review highlights that antivirals such as Tecovirimat, Cidofovir and Brincidofovir have shown efficacy in in vitro and animal 	<ul style="list-style-type: none"> ● A report by the Ontario Ministry of Health dated 28 May 2022 provides guidance for the Imvamune vaccine as post-exposure prophylaxis (PEP) <ul style="list-style-type: none"> ○ Imvamune is a live third generation replication deficient smallpox vaccine, developed to provide an alternative for the vaccination of immunocompromised individuals with atopic dermatitis who could not receive replicating smallpox vaccines ● In the U.K., the Health Security Agency has released interim guidance about the de-isolation and discharge of monkeypox-infected patients, which pertains both to patients admitted to hospitals as well as those who manage symptoms at homes

	<p>studies, but their effectiveness in humans is unknown (Published 12 November 2020)</p> <ul style="list-style-type: none"> ○ Cidofovir and Brincidofovir may be considered in severe cases of monkeypox ○ Brincidofovir may have an improved safety profile compared to Cidofovir ○ Human clinical trials of Tecovirimat suggested that the drug was safe and tolerable with only minor side effects <ul style="list-style-type: none"> ● A non-systematic review noted that the recent development of Tecovirimat (and its license in Nigeria) as an antipoxvirus cure is an important achievement in antiviral therapy (Published April 2019) ● A single study examining monkeypox outbreaks in Africa concluded that robust disease surveillance systems with initial and long-term financial and human resource investment are required to stop the spread of monkeypox (published 16 March 2018) <ul style="list-style-type: none"> ○ Coordination of interventions and routine sharing of information between human and wildlife sectors is necessary because monkeypox is a zoonotic disease ● A single study of pregnant women infected with monkeypox in the Democratic Republic of Congo noted that during hospitalization, pregnant women received antibiotics (amoxicillin, chloramphenicol via eye drops, and erythromycin, as well as gentamycin, if necessary) for prevention or control of bacterial superinfection, paracetamol and papaverine were given as analgesics, metronidazole and mebendazole were administered for giardiasis and other intestinal parasitic infections, and quinine as given for malaria (17 October 2017) 	<ul style="list-style-type: none"> ● All jurisdictions highlight that treatment for monkeypox is mainly supportive ● While most patients recover well with only supportive care, some patients may need pain medication, intravenous fluids, and viral medications for severe cases. ● Recently, the European Union approved Tecovirimat to help treat monkeypox infections (but its availability is currently limited) ● CDC lists antivirals Cidofovir, Brincidofovir and Tecovirimat as possible treatments for severe cases of monkeypox, but that their clinical effectiveness in humans have not yet been confirmed ● Additionally, several countries note that smallpox vaccines, antivirals, and vaccinia immune globulin may be used during the first few days of someone who may have been infected as a preventive measure to help control outbreaks

To help health- and social-system leaders as they respond to pressing challenges, the McMaster Health Forum prepares rapid evidence profiles like this one. This rapid evidence profile was commissioned by the Office of the Chief Science Officer, Public Health Agency of Canada. The authors would like to thank Parm Toor for support in preparing the profile, as well as Qi Wang and Meixuan Li for appraising the quality of guidelines. The opinions, results, and conclusions are those of the McMaster Health Forum and are independent of the funder. No endorsement by the Public Health Agency of Canada is intended or should be inferred.

Appendix 1: Methodological details

We use a standard protocol for preparing living evidence profiles (LEP) to ensure that our approach to identifying research evidence as well as experiences from other countries and from Canadian provinces and territories are as systematic and transparent as possible in the time we were given to prepare the profile.

Identifying research evidence

For this LEP, we searched [ACCESSSS](#), [HealthEvidence](#), [Health Systems Evidence](#), [PubMed](#) and [MedRxiv](#) for:

- 1) guidelines (defined as providing recommendations or other normative statements derived from an explicit process for evidence synthesis);
- 2) full systematic reviews;
- 3) rapid reviews;
- 4) protocols for reviews or rapid reviews that are underway;
- 5) titles/questions for reviews that are being planned; and
- 6) single studies (when no guidelines, systematic reviews or rapid reviews are identified).

In each database we used the open search function for monkey pox OR monkeypox. In PubMed, we used the MeSH headings of monkeypox and monkeypox virus combined with open text terms of monkeypox and monkey pox. All searches were limited to literature published from 2017 onwards to capture any evidence related to recent outbreaks outside Africa.

Each source for these documents is assigned to one team member who conducts hand searches (when a source contains a smaller number of documents) or keyword searches to identify potentially relevant documents. A final inclusion assessment is performed both by the person who did the initial screening and the lead author of the rapid evidence profile, with disagreements resolved by consensus or with the input of a third reviewer on the team. The team uses a dedicated virtual channel to discuss and iteratively refine inclusion/exclusion criteria throughout the process, which provides a running list of considerations that all members can consult during the first stages of assessment.

During this process we include published, pre-print and grey literature. We do not exclude documents based on the language of a document. However, we are not able to extract key findings from documents that are written in languages other than Chinese, English, French or Spanish. We provide any documents that do not have content available in these languages in an appendix containing documents excluded at the final stages of reviewing.

Identifying experiences from other countries and from Canadian provinces and territories

For each LEP, we collectively decide on what countries to examine based on the question posed. For other countries we searched relevant government and stakeholder websites. In Canada, we search websites from relevant federal and provincial governments, ministries and agencies (e.g., Public Health Agency of Canada).

While we do not exclude countries based on language. Where information is not available in English, Chinese, French or Spanish, we attempt to use site-specific translation functions or Google translate.

Assessing relevance and quality of evidence

We assess the relevance of each included evidence document as being of high, moderate or low relevance to the question. We then use a colour gradient to reflect high (darkest blue) to low (lightest blue) relevance.

Two reviewers independently appraised the quality of the guidelines we identified as being highly relevant using AGREE II. We used three domains in the tool (stakeholder involvement, rigour of development and editorial independence) and classified guidelines as high quality if they were scored as 60% or higher across each of these domains.

Two reviewers independently appraise the methodological quality of systematic reviews and rapid reviews that are deemed to be highly relevant. Disagreements are resolved by consensus with a third reviewer if needed. AMSTAR rates overall methodological quality on a scale of 0 to 11, where 11/11 represents a review of the highest quality. High-quality reviews are those with scores of eight or higher out of a possible 11, medium-quality reviews are those with scores between four and seven, and low-quality reviews are those with scores less than four. It is important to note that the AMSTAR tool was developed to assess reviews focused on clinical interventions, so not all criteria apply to systematic reviews pertaining to health-system arrangements or to economic and social responses to COVID-19. Where the denominator is not 11, an aspect of the tool was considered not relevant by the raters. In comparing ratings, it is therefore important to keep both parts of the score (i.e., the numerator and denominator) in mind. For example, a review that scores 8/8 is generally of comparable quality to a review scoring 11/11; both ratings are considered 'high scores.' A high score signals that readers of the review can have a high level of confidence in its findings. A low score, on the other hand, does not mean that the review should be discarded, merely that less confidence can be placed in its findings and that the review needs to be examined closely to identify its limitations. (Lewin S, Oxman AD, Lavis JN, Fretheim A. SUPPORT Tools for evidence-informed health Policymaking (STP): 8. Deciding how much confidence to place in a systematic review. *Health Research Policy and Systems* 2009; 7 (Suppl1):S8.

Preparing the profile

Each included document is hyperlinked to its original source to facilitate easy retrieval. For all included guidelines, systematic reviews, rapid reviews and single studies (when included), we prepare a small number of bullet points that provide a brief summary of the key findings, which are used to summarize key messages in the text. Protocols and titles/questions have their titles hyperlinked given that findings are not yet available. For this profile, we only prepared bulleted summaries of key findings for documents deemed to be of high relevance. For those classified as medium or low relevance, we list the title with a link to the primary source for easy retrieval if needed. We then draft a brief summary that highlights the total number of different types of highly relevant documents identified (organized by document), as well as their key findings, date of last search (or date last updated or published), and methodological quality.

Appendix 2a: Key findings from new evidence documents that address the question, organized by document type, and sorted by relevance to the question and monkeypox

Type of document	Relevance to question	Key findings	Recency or status
Guidelines	<ul style="list-style-type: none"> Prevention and control Prognosis Treatment 	<ul style="list-style-type: none"> These guidelines provide a clinical management algorithm for pregnant women with suspected monkeypox virus exposure, including isolation and fetal surveillance recommendations It is recommended that all cases of monkeypox virus in pregnancy are reported to WHO and an international registry for emerging pathogens Tecovirimat and vaccinia immune globulin can be considered for pregnant women who are severely ill <p>Source (X-quality AGREE II rating; published in The Lancet)</p>	Published 2 July 2022
Full systematic reviews	None identified		
Rapid reviews	None identified		
Non-systematic reviews	<ul style="list-style-type: none"> Prevention and control 	<ul style="list-style-type: none"> This review found that vaccinia viruses can be inactivated on artificially contaminated surfaces by 70% ethanol (≤ 1 minute), 0.2% peracetic acid (≤ 10 min) and 1% to 10% of a probiotic cleaner (1 h) Hydrogen peroxide (14.4%) and iodine (0.04% - 1%) were effective in suspension tests, sodium hypochlorite (0.25% - 2.5%; 1 min), 2% glutaraldehyde (10 min) and 0.55% ortho-phthalaldehyde (5 min) were effective on artificially contaminated surfaces Copper (99.9%) was equally effective against vaccinia virus and monkeypox virus in 3 minutes <p>Source</p>	Published 28 June 2022
Protocols for reviews that are already underway	<ul style="list-style-type: none"> Epidemiology 	<ul style="list-style-type: none"> The epidemiology of monkeypox disease <p>Source</p>	Anticipated completion 8 July 2022
	<ul style="list-style-type: none"> Epidemiology Clinical presentation 	<ul style="list-style-type: none"> Global epidemiological and clinical characteristics of monkeypox cases: A Systematic review, 1970–2022 <p>Source</p>	Anticipated completion 16 July 2022

	<ul style="list-style-type: none"> Epidemiology 	<ul style="list-style-type: none"> Prevalence of monkeypox transmission by sexual contact transmission: Systematic review Source 	Anticipated completion 30 July 2022
Titles and questions for reviews being planned	None identified		
Single studies	<ul style="list-style-type: none"> Epidemiology (including transmission) 	<ul style="list-style-type: none"> This study documented the creation of an open-access database to track the occurrence of cases in different countries, as well as information on age, gender, dates of symptom onset and laboratory confirmation symptoms, locations, travel history, and additional metadata During early stages of outbreaks, it was found that retrieving reliable data on the characteristics of cases at a global scale is challenging Working with the WHO Hub for Pandemic and Epidemic Intelligence, the team is defining a contact data schema allowing countries and researchers to estimate key epidemiological parameters such as incubation period and serial interval across various settings Source 	Published 1 July 2022
	<ul style="list-style-type: none"> Epidemiology (including transmission) 	<ul style="list-style-type: none"> This study built dynamic models to mimic the spread of the monkeypox virus (MPX) as an emerging zoonosis in a hypothetical metropolitan area, including high- and low-risk transmission among humans and animals to humans The model followed the SEIR framework to include 1) Infectious (prodromal phase); 2) Infectious (rash phase); 3) Isolated (infectious); and 4) Isolated (susceptible) subpopulations Transmission in the human population was modelled using a transmission risk parameter and a contact matrix that describes contacts between and within-population subgroups Additionally, the authors modelled the spread of the MPX virus in humans considering animal hosts like rodents (e.g., rats, mice, squirrels, chipmunks, etc.) and emphasize their role and transmission of the virus in a high-risk group, including men-who-have-sex-with-men 	Published 29 June 2022

		<ul style="list-style-type: none"> • The results showed that the MPX virus may spill over from high-risk groups (e.g., men-who-have-sex-with-men) to broader populations if efficiency of transmission increases in the higher-risk group • The risk of outbreak can be greatly reduced if at least 65% of symptomatic cases can be isolated and their contacts traced and quarantined <p>Source</p>	
	<ul style="list-style-type: none"> • Biology 	<ul style="list-style-type: none"> • This study found that the monkeypox virus outbreak described so far in non-endemic countries belongs to clade 3 and most likely has a single origin • A mutational analysis shows signs of potential monkeypox human adaptation in ongoing microevolution <p>Source</p>	Published 24 June 2022
	<ul style="list-style-type: none"> • Epidemiology (including transmission) 	<ul style="list-style-type: none"> • This study conducted an online survey of the United States' (US) general public about their knowledge and attitudes, their trusted sources of information, and to test whether COVID-19 vaccination status was associated with monkeypox vaccination attitudes or intentions to receive one if it was recommended • The survey included 856 participants, of which 51% was female, 41% had a college degree or higher and 38% was 55 years or older, which was similar to the US population • Sources of information deemed most reliable to convey information about the outbreak were healthcare professionals, health officials (e.g., Centers for Disease Control and Prevention), and social media accounts of healthcare professionals and researchers • Almost half the respondents (47%) feel that their knowledge level about Monkeypox is poor or very poor • Current COVID-19 vaccination status was a strong predictor of positive intentions of receiving a monkeypox vaccination if recommended • The low levels of knowledge about monkeypox indicate the need for more clear communication about the outbreak <p>Source</p>	Published 23 June 2022

	<ul style="list-style-type: none"> • Epidemiology (including transmission) 	<ul style="list-style-type: none"> • Using a modelling framework, the authors modelled a monkeypox outbreak in a simulated population of 50 million people with socioeconomic and demographic characteristics of a high-income European country • The baseline scenarios projected that with no public health emergency interventions, monkeypox could lead to small national outbreaks of moderate duration, but they would all subside in 23 to 37 weeks, depending on the number of cases introduced • Contact tracing with isolation of symptomatic cases would reduce the number of secondary cases by 72.2% following the introduction of 3 cases, 66.1% after 30 cases, and 68.9% after 300 cases • Adding ring vaccination to contact tracing would reduce the number of secondary cases by 77.8% following the introduction of 3 cases, 78.7% after 30 cases, and 86.1% after 300 cases <p>Source</p>	Published 23 June 2022
	<ul style="list-style-type: none"> • Diagnosis 	<ul style="list-style-type: none"> • The study developed a real-time PCR assay • Five of the 10 clinical samples tested positive within the detectable range • The authors concluded that their real-time qPCR assay could be utilized in the multi-country outbreak <p>Source</p>	Last updated 23 June 2022 (Pre-print)
	<ul style="list-style-type: none"> • Prevention and control 	<ul style="list-style-type: none"> • This study estimated the incubation period of the monkeypox virus (MPX) using United States data from 22 probable and confirmed patient cases reported from 17 May 2022 to 6 June 2022 • The incubation period was estimated from exposure to first symptom onset • All 22 monkeypox patients included in the analysis were male, with a median age of 37 years • Commonly reported symptoms included lesions in the anal and genital areas, swollen lymph nodes, rectal pain, headache, and fatigue • The mean incubation period from exposure to first symptom onset was 7.6 days and the 95th percentile was 17.1 days 	Published 21 June 2022

		<ul style="list-style-type: none"> The results align with the current Centers for Disease Control and Prevention’s recommendations for monitoring close contacts of people with monkeypox for 21 days after their last exposure <p>Source</p>	
	<ul style="list-style-type: none"> Biology 	<ul style="list-style-type: none"> This study evaluates the performance and added value of the MinION real-time TGS sequencing device for sequencing the complete genome of a MPXV strain, obtained from a pustular lesion in a remote area of Central Africa MinION sequencing has been used to study other epidemics and it has helped link congenital malformations to the Zika virus A total of 146,920 raw reads were obtained with sizes ranging from 66 bp to 68 kb for a median of 1946 bp It was concluded that the data obtained from directly sequencing DNA extracted from a lesion is sufficient to complete the genome of the virus <p>Source</p>	<p>Published 24 June 2022</p>

Appendix 2b: Key findings from evidence documents that address the question, organized by document type and sorted by relevance to the question and monkeypox

Appendix 4: Experiences in other countries related to available evidence about monkeypox [yellow highlights = newly added or revised content in this version of the living evidence profile]

Country	Summary of experiences
Australia	<p>Biology</p> <ul style="list-style-type: none"> The government of Australia characterizes monkeypox as a viral zoonotic self-limited disease with symptoms lasting two to four weeks <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> As of 6 July 2022, the government of Australia has reported 17 confirmed cases of monkeypox, including five in Victoria, 11 in New South Wales, and one in South Australia The government of Australia indicates that human-to-human transmission can occur through close contact with large lesions on the skin typically around the head and neck, body fluids (including respiratory droplets), and contaminated materials <ul style="list-style-type: none"> The government of Australia noted that transmission can likely occur between sexual partners due to intimate contact with infectious skin lesions <p>Prevention and control</p> <ul style="list-style-type: none"> The government of Australia indicated that they have a vaccine available (in addition to treatments) and provided clinical guidance <ul style="list-style-type: none"> ACAM2000™ (smallpox vaccine) is available to be used for PEP (e.g., healthcare workers, household contacts, or contacts in other settings) and PrEP (e.g., healthcare workers, laboratory worker), but cannot be used in individuals with severely immunocompromised conditions, people who are pregnant, people with active eczema or other active skin conditions, people with allergies, and children under 12 months Individuals who have received a smallpox vaccine in the past are not recommended to be revaccinated with ACAM2000 The effectiveness of smallpox vaccine against monkeypox (PrEP) is 80.7% with limited available evidence on duration of protection and effectiveness of the vaccine used as PEP ACAM2000™ is associated with a risk of myopericarditis, with other reported serious adverse events such as eczema vaccinatum, generalized vaccinia, progressive vaccinia, fetal vaccinia, neurological adverse events Vaccination aftercare involves the expected reaction (e.g., papule, blister, pustule, scab, permanent pitted scar) The JYNNEOS vaccine is not registered or available in Australia The government of Australia recommends medical advice for those who have recently traveled overseas or in contact with a case in Australia The New South Wales government recommends the following prevention measures: 1) self-isolation until rash is fully resolved; 2) proper hand hygiene; 3) use of PPE around people infected with monkeypox; and 4) avoid contact with materials from a person infected with monkeypox (e.g., bedding) On 1 June 2022, monkeypox became a nationally notifiable disease for six months The government of Australia has convened national expert groups to develop treatment and vaccine guidelines On 3 June 2022, the government of Australia released a public video to answer top three questions about monkeypox <p>Clinical presentation</p> <ul style="list-style-type: none"> A recent Eurosurveillance case report described a case of MPX infection in an individual returning from Europe

	<ul style="list-style-type: none"> ○ The individual reported a genital rash, followed by a fever and lymphadenopathy, which then led to diffuse rash with few lesions present on the face and extremities ○ The individual was admitted to the hospital and managed with contact and airborne precautions in a single room with negative pressure ventilation ○ The case report concluded that normal CD4+ T-cell count and suppressed HIV viral load on antiretroviral therapy were potential important factors in preventing more severe outcomes ● The government of Australia indicates that the incubation period is between six to 13 days <ul style="list-style-type: none"> ○ Symptoms during one to five days include fever, rash, and swelling of lymph nodes ○ A rash usually occurs within one to three days around the face, arms, and legs in appearance of a fever <p>Diagnosis</p> <ul style="list-style-type: none"> ● The government of Australia indicates that monkeypox is confirmed with laboratory testing and clinical assessment <p>Treatment</p> <ul style="list-style-type: none"> ● The New South Wales government described that the disease is mild, but some patients may need pain medication, intravenous fluids, and viral medications for severe cases
Belgium	<p>Biology</p> <ul style="list-style-type: none"> ● Monkeypox is zoonotic disease caused by an orthopoxvirus <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> ● As of 6 July 2022, Belgium has reported a total of 168 Monkeypox cases within the country ● An individual may be infected with Monkeypox if they come into contact with bodily fluids, mucous membranes, saliva droplets, and contaminated surfaces (e.g., bedding, towels, linen) of an infected individual ● Transmission of Monkeypox can also occur from infected animals through direct contact with blood or a bite ● Researchers at the University of Antwerp and Institute of Tropical Medicine reported nearly a full genome of a Belgium male who tested positive for Monkeypox and found that this case was linked to the Monkeypox outbreak in Portugal <p>Prevention and control</p> <ul style="list-style-type: none"> ● Belgium was the first country to announce a mandatory 21-day quarantine period for individuals infected with Monkeypox <p>Clinical presentation</p> <ul style="list-style-type: none"> ● The most common symptoms that appear after infection are fever, muscle aches, and a headache, which are usually followed by skin lesions (blisters and lumps) appearing over the entire body ● Rashes on the palms of the hands and soles of the feet are a characteristic of the disease <p>Diagnosis</p> <ul style="list-style-type: none"> ● The Institute for Tropical Medicine (ITM) located in Antwerp, Belgium has been permitted to conduct polymerase chain reaction (PCR) tests to detect Monkeypox, and to use samples of the vesicles and scabs on the skin for analysis <p>Prognosis</p> <ul style="list-style-type: none"> ● The incubation period is typically between six and 13 days but it can range anywhere from five to 21 days ● The disease is usually mild, with the illness lasting two to four weeks in length <p>Treatment</p>

	<ul style="list-style-type: none"> • Currently, there are no approved treatments for Monkeypox, however, individuals typically recover on their own after a few weeks
France	<p>Biology</p> <ul style="list-style-type: none"> • Monkeypox is a rare viral infectious disease caused by an orthopoxvirus <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • As of 5 July 2022, there have been 577 confirmed cases of Monkeypox in France, with 387 reported in Ile-de-France, 52 reported in Auvergne-Rhône-Alpes, 37 reported in Occitanie, 30 in New Aquitaine, eight in Normandie, 23 in Hauts-de-France, one in Centre-val de Loire, four in Pays-de-la-Loire, 21 in Provence-Alpes-Côte d'Azur, three in Bourgogne-Franche-Comté, six in Grand-Est, and five in Brittany • The primary mode of disease transmission is from rodent-to-human, however, it can also be transmitted from human-to-human through direct contact with skin lesions, mucous membranes, respiratory droplets (which require prolonged face-to-face contact), and contaminated surface environments (e.g., bedding, clothes, dishes, and linen) of infected individuals <p>Prevention and control</p> <ul style="list-style-type: none"> • Currently, it is recommended that infected individuals complete a full isolation period of three weeks until the disappearance of all the scabs • The infected individual is contagious upon the appearance of their first symptom(s) • On 24 May 2022, the French National Authority for Health released a recommendation to launch their targeted vaccination strategy to help reduce the transmission of the Monkeypox virus <ul style="list-style-type: none"> ○ This will include vaccinations for at-risk adults (e.g., exposed healthcare professionals) who have been in contact with infected individuals ○ Vaccinations should occur within the first two weeks of exposure (ideally within the first four days), using a two-dose regimen that are given 28 days apart from each other ○ The vaccine regimen is to be increased to three doses for immunocompromised individuals • The French National Authority for Health published a press release outlining their vaccine strategy for two population groups: 1) those who have been vaccinated against smallpox in their childhood; and 2) children. <ul style="list-style-type: none"> ○ The recommendation involves a single vaccine dose for at-risk contacts who have been vaccinated against smallpox prior to 1980, and stated that vaccination of minors is to be considered on a case-by-case basis by a specialist who will do a robust assessment of the benefits and risks <p>Clinical presentation</p> <ul style="list-style-type: none"> • An infection caused by the Monkeypox virus initially presents with a fever, headaches, body aches, and asthenia, which is followed by the appearance of fluid-filled blistering rashes that eventually dry out over time and leave behind a scab and scar • The blistering rashes typically appear on the face, hands (palms), and feet (soles), while the mouth, genital area, and lymph nodes can all be affected too • Of the cases investigated in the country, the most commonly reported symptoms are a genito-anal rash, eruption on another part of the body, fever, and lymphadenopathy <p>Diagnosis</p> <ul style="list-style-type: none"> • Among the new cases reported on 5 July 2022, three new Monkeypox cases were detected in females and one was reported in a child <p>Prognosis</p>

	<ul style="list-style-type: none"> • The incubation period of the disease can range from five to 21 days, with the initial fever lasting anywhere from one to three days • The disease is reportedly more severe in children and immunocompromised individuals, as there is the possibility of superinfections of skin lesions or further complications arising from existing respiratory, digestive, ophthalmological, or neurological disorders <p>Treatment</p> <ul style="list-style-type: none"> • It is reported that this disease tends to spontaneously heal on its own, with the majority of individuals recovering within two to four weeks
Germany	<p>Biology</p> <ul style="list-style-type: none"> • Monkeypox is an infectious disease caused by the monkeypox virus Orthopoxvirus simiae <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • As of 7 July 2022, there are 1,385 confirmed cases of Monkeypox across all 16 federal states in Germany • The primary mode of transmission of Monkeypox to humans is from rodents, however it can also be transmitted through close contact with an infected individual or contaminated surface(s) • On 19 May 2022, the first confirmed case of Monkeypox was reported in Germany <p>Prevention and control</p> <ul style="list-style-type: none"> • In conjunction with the Robert Koch Institute (RKI), the Ministry of Health (BMG) has put forth a recommendation to help assist federal states in responding to the Monkeypox outbreak, and a key feature of this recommendation includes ordering an isolation period of at least 21 days for infected individuals • On 30 May 2022, RKI released a recommendation on hygiene measures for the treatment and care of patients diagnosed with Monkeypox in health care facilities <ul style="list-style-type: none"> ○ This includes the use of hand disinfectant, disposable medical gloves, personal protective equipment and providing spatial accommodation (i.e., single rooms for infected patients) • As a preventative measure, Germany has ordered 40,000 smallpox vaccine doses, with an additional 200,000 more set to follow afterwards • The Standing Committee on Vaccination (STIKO) has put forth a recommendation to vaccinate individuals against the Monkeypox virus with Imvanex <ul style="list-style-type: none"> ○ This includes vaccinations for certain population groups, including 1) post-exposure prophylaxis upon Monkeypox exposure in asymptomatic individuals aged 18 years and older (e.g., those who have had close physical contact with individuals with Monkeypox); 2) individuals with an increased risk of exposure and infection during a potential outbreak (e.g., men aged 18 years and older with same-sex sexual contacts or multiple partners); and 3) immunocompromised individuals ○ For those who have not previously been vaccinated against smallpox, immunization with Imvanex is a two-dose regimen separated 28 days apart, while a single dose is sufficient for those with a previous smallpox vaccine (barring immunocompromised individuals who would still receive two doses in either case) • RKI published a recommendation for the management of close contacts of Monkeypox cases, which includes quarantining of individuals with a high risk of transmission, such as household members <p>Clinical presentation</p> <ul style="list-style-type: none"> • The symptoms include a fever, swollen lymph nodes, skin rashes, pain, and itching in the genital area <p>Diagnosis</p>

	<ul style="list-style-type: none"> • The virus can be detected using polymerase chain reaction (PCR) and the particles can further be detected through an electron microscope <p>Prognosis</p> <ul style="list-style-type: none"> • The incubation period is normally between six and 13 days but it can range anywhere from five to 21 days • Monkeypox cases are usually mild and people recover within the span of a few weeks, though there may be instances of severe cases that arise within the population <p>Treatment</p> <ul style="list-style-type: none"> • Tecovirimat was recently approved in the European Union to help treat Monkeypox infections (however its availability is currently limited)
Italy	<p>Biology</p> <ul style="list-style-type: none"> • Human monkeypox virus is a double-stranded DNA virus <ul style="list-style-type: none"> ◦ Two genetic clades have been characterized: West African and Central African <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • Over the past five decades, monkeypox outbreaks have been reported in 10 African countries and four countries outside of Africa, and to date, 118 cases of monkeypox have been reported in non-endemic countries <ul style="list-style-type: none"> ◦ The phylogenetic characteristics of the virus supports the hypothesis of a introduction of the West African clade into non-endemic countries • A rapid communications report dated 26 May 2022 reported 4 cases in Italy from 17 and 22 May 2022 <ul style="list-style-type: none"> ◦ All patients had travelled in the first two weeks of May, 3 participated in a mass gathering event, and 1 travelled for sex work, having condomless sexual intercourse with different male partners ◦ All patients had a history of sexually transmitted infections • A letter to the editor dated 9 June 2022 reported a total of 29 PCR-confirmed cases <ul style="list-style-type: none"> ◦ 23/29 travelled abroad and most of them (13/23) had vacationed on the Canary Islands ◦ There was transmission of two generations of locally acquired cases related to an index case returning to Italy from Ghana <p>Prevention and control</p> <ul style="list-style-type: none"> • The four monkeypox patients in the rapid communications report dated 26 May 2022 were taken to hospitals with combined droplet and contact isolation measures; they were also given filter face piece-2 (FFP2) for care management • The Italian Ministry of Health issued a variety of recommendations: case notification, protective measures for healthcare workers, contact tracing, possibly implementing quarantine measures, as well as providing non-stigmatizing information to at-risk populations <p>Clinical presentation</p> <ul style="list-style-type: none"> • In the rapid communications report dated 26 May 2022, lesions of the four patients appeared 1-3 days after systemic symptoms, clustered or isolated, beginning as raised itchy papules secreting serous with central umbilication, and over days, the umbilication widened until the lesion opened and the scab formed 2 weeks after symptom onset • Patient one, a male in his 30s had been treated with oral ciprofloxacin and acyclovir, and 1 single dose of benzylpenicillin for skin lesions during his travels in mid-May <ul style="list-style-type: none"> ◦ At admission, multiple asynchronous deep-seated and well-circumscribed lesions with central umbilication were present on his genital area, with inguinal lymphadenopathy

	<ul style="list-style-type: none"> ○ A single lesion was present on the anterior and posterior thorax and on the left calf ● Patient one, a male in his 30s, had been taking daily-PreP, and was admitted for fever and asthenia starting in mid-May <ul style="list-style-type: none"> ○ 3 days later, perianal lesions appeared and presented as raised, itchy papules secreting serious, with concomitant painful inguinal lymphadenopathy ○ Multiple anal lesions appeared over the next 3 days, followed with lesions on the back, legs, and sole of one foot ● Patient three, a male in his 30s was admitted for a 2-day fever and clustered itchy popular lesions in the anal region and single lesions on head, thorax, legs, arms, hand and penis <ul style="list-style-type: none"> ○ He reported getting a smallpox vaccination during childhood ● Patient four, a male in his 30s was taking event-driven PreP, and was admitted for a 2-day history of myalgia <ul style="list-style-type: none"> ○ Vesicular-papular genital lesions appeared, followed by further skin lesions that appeared 6 days later in the suprapubic area and chest ● In all patients, skin lesions had an asynchronous evolution ● A letter to the editor dated 9 June 2022 reported a total of 29 PCR-confirmed cases <ul style="list-style-type: none"> ○ 28/29 cases were males, and 16/18 reported having sex with other men ○ The median age of patients was 36 years ○ All presented with a rash, and in 18/21 cases, the rash was localized in the genital/perianal area ○ Fever was reported in 12/22 cases for whom information was available <p>Diagnosis</p> <ul style="list-style-type: none"> ● In the rapid communications report dated 26 May 2022, the four patients were positive for monkeypox DNA in real-time PCR using samples from skin, genital and anal lesions, serum, plasma, seminal fluid, feces, and the nasopharynx <ul style="list-style-type: none"> ○ Viral DNA was extracted by Qiamp Viral RNA mini kit (Qiagen) and 2 real-time PCRs using a Real-Star Orthopoxvirus PCR kit and a G2R_G assay which was used as a confirmatory PCR ○ Sanger sequencing was used to identify which of the 2 clades the virus belonged to <p>Treatment</p> <ul style="list-style-type: none"> ● In the rapid communications report dated 26 May 2022, only patient 2 used anti-inflammatory and antihistaminic drugs for perianal pain and general itch <ul style="list-style-type: none"> ○ The other patients recovered spontaneously, without antiviral therapy
Netherlands	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> ● Monkeypox occurs mostly in West and Central Africa, mainly infecting rodents <ul style="list-style-type: none"> ○ Monkeypox is described as a zoonosis (a disease that can be transmitted from animals to humans) ○ The virus can enter through mucous membranes (mouth, nose, eyes) and open wounds, and can also be spread through droplets from blisters or from mouth and pharynx ○ It cannot be spread through droplets floating in the air ● It is suspected that many people have been infected with monkeypox through contact among men who have sex with men <ul style="list-style-type: none"> ○ The variant currently in Europe is not particularly infectious, but there is a lack of understanding in how it has spread to those who are currently sick ● As of 31 May 2022, 31 cases were confirmed by PCR ● As of 16 June 2022, there were 95 cases of monkeypox in the country

	<p>Prevention and control</p> <ul style="list-style-type: none"> • According to the Government of the Netherlands, infected individuals must undergo isolation at home <ul style="list-style-type: none"> ○ High-risk contacts such as sexual partners, family members, and others in contact with the skin blisters should also quarantine ○ If they take a test and it is negative, they can end their isolation ○ If they are positive, they should continue isolating until no longer being infectious and their skin is healed completely and the scabs have fallen off their skin • The Municipal Public Health Service will begin source and contact tracing if someone tests positive <p>Clinical presentation</p> <ul style="list-style-type: none"> • Symptoms are described as mild, including fever, headache, muscle ache, swollen lymph nodes, chills, and fatigue <ul style="list-style-type: none"> ○ 1-3 days later, an infected person will get a rash that starts on the face and appears on the rest of the body ○ The rash will start as spots that develop, which form scabs that fall off the skin in 2-3 weeks ○ In most cases, the rash started in the anus and pubic region before spreading to the rest of the body • As of 31 May 2022, all 31 cases were men and identified as MSM with an age range of 23-64 years <ul style="list-style-type: none"> ○ 18 cases had reported symptom onset and the most likely date of exposure related to attending an event ○ The 97.5 percentile for the incubation period is estimated to be 19.9 days, and an estimated 2% of all cases would develop symptoms more than 21 days after being exposed ○ The literature indicates that incubation periods differ by route of transmission (non-invasive exposure through skin or droplets is 13 days, and complex and invasive exposure through contact with broken skin or mucous membranes is 9 days), which is consistent with smallpox ○ The authors' estimate of mean incubation period for monkeypox is 8.5 days and all current cases are MSM with lesions in the anal and genital regions, which is consistent with the invasive contact incubation period of 9 days reported in the literature <p>Diagnosis</p> <ul style="list-style-type: none"> • The Netherlands confirmed the first cases of monkeypox on 20 May 2022 • The Health Minister designated monkeypox as a category A disease on 24 May 2022, meaning that doctors must report new or suspected cases immediately to prevent its spread <p>Treatment</p> <ul style="list-style-type: none"> • According to the National Institute of Public Health and the Environment, the current smallpox vaccine can be used during the first few days of possible infection, and can be used preventatively in people at greater risk of infection
Portugal	<p>Biology</p> <ul style="list-style-type: none"> • The government of Portugal characterizes monkeypox as a disease that is transmitted through contact with infected animals, people, or contaminated materials, which is often rare and does not easily spread among humans <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • As of 1 July 2022, Portugal has reported 415 confirmed cases <ul style="list-style-type: none"> ○ Most cases have been reported in Lisbon and Vale do Tejo ○ All cases are among men between the ages of 19 and 61, with majority under the age of 40 years and older ○ All cases are stable and under clinical follow-up

	<ul style="list-style-type: none"> • A Eurosurveillance case report from 29 April to 23 May 2022 described the preliminary results of the outbreak investigation and the epidemiological characteristics of 27 confirmed cases <ul style="list-style-type: none"> ○ The report found that all cases were among young men age ranging from 20 to 59 years ○ Most commonly reported symptoms include exanthema, inguinal lymphadenopathy, fever, asthenia, headache, genital ulcers and vesicles ○ 14 men reported to also have HIV infection ○ The authors concluded that the MPX outbreak in Portugal shows signs of sustained transmission among a susceptible demographic group (given the lack of exposure to the smallpox vaccination), in addition to hypothesizing that MPX has been circulating below the detection of the surveillance systems • The Directorate-General for Health suggested that transmission is occurring through close contact, including sexual intercourse <p>Prevention and control</p> <ul style="list-style-type: none"> • A Eurosurveillance case report from 29 April to 23 May 2022 described the preliminary results of the outbreak investigation and the epidemiological characteristics of 27 confirmed cases <ul style="list-style-type: none"> ○ The Public Health Emergencies Centre and the Health Authorities in Portugal reported that home isolation was recommended until lesions fade away, and self-monitoring for 21 days from the date of last exposure ○ Healthcare workers are recommended to use standard contact precautions, hand hygiene, and barrier nursing through PPE (i.e., gloves, face mask, gown, goggles) ○ Other measures include identifying the first case, use of standard case definition with prompt sample collection for diagnosis ○ Public health authorities are also engaging with LGBTIQI+ communities, including community leaders, on targeted risk communication and social mobilisation with non-stigmatising approaches • The Directorate-General for Health disseminated communication materials related to transmission, prevention, and hygiene measures to reduce the risk of monkeypox <ul style="list-style-type: none"> ○ Dissemination activities include raising awareness at public and private events <p>Clinical presentation</p> <ul style="list-style-type: none"> • The government of Portugal indicated that individuals should seek medical attention if they have ulcerative lesions, rash, enlarged lymph nodes
Spain	<p>Biology</p> <ul style="list-style-type: none"> • The Ministry of Health of Spain has developed a guideline for the management of the Monkeypox, which defines Monkeypox (MPX) as a rare viral zoonotic disease <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • As of 1 July 2022, the Public Health Agency has confirmed around 1.200 cases of orthopoxvirus in Spain, with Madrid and Catalonia are the most affected • The first human cases were identified in the Democratic Republic of the Congo in 1970 <ul style="list-style-type: none"> ○ While the majority of documented cases of MPX have occurred in the Democratic Republic of the Congo, the number of cases in other West and Central African countries has increased during the last decade

- Since 2016, confirmed cases of MPX have been reported in the Central African Republic, the Democratic Republic of the Congo, Liberia, Nigeria, the Republic of the Congo, and Sierra Leone, and several African countries in these regions are currently experiencing active outbreaks of MPX
- Outside of Africa, cases of human MPX infections have been documented in different countries: 47 cases in the United States in 2003 and one in 2021, four cases in the United Kingdom (UK) in 2018/2019 and three in 2021, one case in Israel in 2018 and a case in Singapore in 2019
- Those diagnosis were confirmed after PCR tests carried out by the laboratory of the National Center for Microbiology (CNM) of the Carlos III Health Institute (ISCIII)
- An Emergency Committee of the World Health Organization [will determine on June 23](#) if orthopoxvirus is an international threat

Prevention and control

- The Government of Spain [will buy vaccines and antivirals](#) to treat monkeypox, and the Minister of Health announced that the government has already negotiated these acquisitions with the European Medicines Agency (EMA), which is the the health emergency preparedness authority and responsible for making the IMvanex vaccine available
- Historically, [smallpox vaccination](#) has been shown to protect partially against MPX
- Public health authorities are [engaging with LGBTQI+ communities](#), on targeted risk communication and social mobilisation with non-stigmatizing approaches
- The Health Minister, Carolina Daria, recalled that Spain has "a significant amount" of vaccines available, [5,300 were acquired by the U.S. Authority](#) and the EU's Health Response (HERA), and 200 from Imvanex that was purchased from another European country

Clinical presentation

- Monkeypox virus infection is usually a self-limited illness, and most people recover within several weeks, however, in some cases serious illness can occur
- The incubation period is 6 to 16 days, but can range from five to 21 days
- The classic initial clinical picture described until this outbreak usually includes fever, headache, muscle aches, lymphadenopathy, and fatigue
- Between one and five days after the onset of fever, a rash develops, often starting on the face and then spreading to other parts of the body with the rash tending to be more concentrated on the face and extremities than on the trunk
- The disease affects the face (in 95% of cases); the palms of the hands and soles of the feet (in 75% of cases); the oral mucosa (in 70% of cases); the genitalia (30%); and the conjunctiva and cornea (20%)
- Areas of erythema or hyperpigmentation of the skin around the lesions are usually seen
- The lesions can vary in size, the rash evolves sequentially from macules to papules, vesicles, pustules, and crusts that dry up and fall off
- In the first reported cases associated with this outbreak, genital and peri-oral lesions have been identified in a high number of cases
- Symptoms usually last between two to four weeks

Diagnosis

- The clinical differential diagnosis that should be considered includes other exanthematous diseases that can present with a generalized pustular or vesicular eruption, such as smallpox (because of the risk that it could be an intentional event), chickenpox, herpes virus,

	<p>eczema herpeticum, some enteroviruses (such as coxsackie or echovirus) measles, bacterial skin infections, scabies, syphilis, drug-associated allergies and some dermatological diseases</p> <ul style="list-style-type: none"> • Lymphadenopathy during the prodromal stage of the disease may be a clinical feature to distinguish MPX from varicella or smallpox • The guideline developed by the Ministry of Health of Spain has recommended that samples to be obtained in a suspected case should be taken from the skin lesion (vesicular fluid, smear of vesicular lesions, exudates or scabs) • The skin lesion sample must be sent in virus transport medium and kept cold • If this sample is not available or additional studies are required, other samples may be used by contacting the National Institution of Microbiology in Spain in advance • Clinical samples are considered category B and, therefore, standard precautions are sufficient for transporting the samples <p>Prognosis</p> <ul style="list-style-type: none"> • The guideline for the management of the Monkeypox developed by the Ministry of Health of Spain has indicated that the number of injuries varies from a few to several thousand and, in severe cases, the lesions may coalesce until large sections of skin are shed • Severe cases occur most often among children, young adults, and immunocompromised persons, and are related to the degree of exposure to the virus and the vulnerability of the person • Complications may include secondary bacterial infections, bronchopneumonia, sepsis, encephalitis, and corneal infection with subsequent loss of vision • Its clinical presentation is milder than smallpox, and the case fatality rate for the West African clade has been documented to be around 1%, while for the Congo Basin clade it can be as high as 10% <p>Treatment</p> <ul style="list-style-type: none"> • Among three antivirals available, the Government of Spain has preferred Tecovimirat, which seems to present the best outcomes • The Government of Spain will join a centralized purchase under the terms agreed with the corresponding pharmaceutical company
Sweden	<p>Biology</p> <ul style="list-style-type: none"> • The Public Health Agency of Sweden defines monkeypox as a rare, sporadic species of the Orthopoxvirus that can be transmitted between animals and humans <ul style="list-style-type: none"> ◦ It has previously infected people in African rainforests where the reservoirs of the virus are primarily wild monkeys <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • According to the U.S. Centers for Disease Control and Prevention’s 2022 Monkeypox Outbreak Global Map, Sweden has confirmed 28 cases of monkeypox as of 6 July 2022 • The Public Health Agency of Sweden reported that the incubation period of monkeypox is usually six to 13 days but can vary between five and 21 days <p>Clinical presentation</p> <ul style="list-style-type: none"> • Symptoms of monkeypox often include mild skin rashes and blisters that can spread to different parts of the body, as well as fever and swollen lymph nodes • If the virus is transmitted sexually, blisters on the genitals and around the anus can occur <p>Diagnosis</p> <ul style="list-style-type: none"> • Sweden confirmed its first case of monkeypox on 19 May 2022, and it is unknown how the person became infected

United Kingdom (U.K.)

Epidemiology (including transmission)

- The case count is [1,351](#) as of 4 July 2022
- Between 7 May 2022 and 16 June 2022, [574 cases](#) of monkeypox have been confirmed in the UK
- The UK passed [legislation to make monkeypox a notifiable disease](#) in law as of 8 June 2022
 - This legislation means that doctors are required to notify their local council or Health Protection Team if they suspect a patient has monkeypox and laboratories must notify the UK Health Security Agency if they identify monkeypox virus in a sample
 - To ensure anyone concerned about monkeypox seeks appropriate healthcare, the National Health Service regulations were amended to make monkeypox treatment and diagnosis free from charge for all overseas visitors
- The UK Health Security Agency has published a [technical briefing investigating the monkeypox outbreak in England](#) which contains sections about the following:
 - Assessed level of the outbreak in England
 - Research and evidence gaps prioritisation
 - Epidemiologic update, including findings from rapid sexual health questionnaires completed by cases
 - Genomic information
 - Transmission dynamics
- The [UK Health Security Agency](#) has reported that a ‘notable proportion’ of cases reported to date have been among individuals who are gay or bisexual and men who have sex with men, and the agency is asking individuals in these groups to be aware of symptoms, especially if they recently had a new sexual partner
- [Contact tracing investigations](#) have identified links to gay bars, saunas, and the use of dating applications in the UK and abroad—but no single factor or exposure that links all cases has been identified
- A [Eurosurveillance report](#) describes the monkeypox outbreak in the UK as of 25 May 2022 that is affecting people with no travel links to endemic countries
 - The mean reporting delay (time between symptom onset and when the case was recorded in the case management system) was 11 days for the 86 cases as of 25 May 2022
 - The outbreak has been grouped into three distinct incidents based on transmission dynamics and travel histories
 - There was a median of four and a maximum of 25 contacts per case; contacts of cases in these incidents included passengers on the same flight as a case, healthcare workers exposed before patients were identified as cases, and community contacts
 - The gay, bisexual, or other men who have sex with men community is overrepresented among the cases, suggesting transmission in these sexual networks
 - While vaccination has been offered to medium- and high-risk contacts uptake has been low, with 69% of healthcare contact and 14% of community contacts having taken up the vaccination offer by 24 May 2022

Prevention and control

- The UK Health Security Agency alongside the public health agencies of England, Scotland, Wales, and Northern Ireland have released a [consensus statement regarding principles for monkeypox control in the UK](#)
 - These principles are intended to guide the public health response to ensure there is a proportionate response that encourages engagement with health services, prevents stigma, and controls spread

- The statement outlines several assumptions about monkeypox transmission and biology that are meant to be regularly updated with new evidence
 - Implications/guidance for the following sectors are presented: community/domestic, ambulatory care, inpatient healthcare, and other residential settings
 - The [UK Health Security Agency](#) has purchased supplies of Imvanex (a smallpox vaccine supplied by Bavarian Nordic) and is offering this vaccine to close contacts of those diagnosed with monkeypox to reduce their risk of symptomatic infection and severe illness
 - High-risk contacts of confirmed cases are also being asked to isolate at home for up to 21 days
 - The smallpox vaccine is also being [offered to health workers](#) who will care for monkeypox patients as well as those who work in sexual health centre and may have assessed suspected cases
 - The UK Health Security Agency is also advising that pregnant and severely immunocompromised workers should not assess or provide care for suspected or confirmed monkeypox cases
 - The [UK Health Security Agency](#) is working with partners to communicate with sexual health service partners as well as the gay, bisexual, or other men who have sex with men community about monkeypox and how to stay safe
 - The agency has noted it is engaging with the dating application Grindr, the LGBT Consortium, Pride organizers, and venue owners to share public health messaging
 - The [UK Health Security Agency](#) notes that appropriate respiratory and contact precautions need to be taken and that scabs may be infectious, so bedding, clothing, and other articles need to be handled appropriately
 - The monkeypox virus is classified as an Advisory Committee on Dangerous Pathogens (ACDP) Hazard Group 3 pathogen and the live virus must be handled at full containment level 3
 - Public Health England has produced a [guidance document about environmental cleaning and decontamination](#) with sections dedicated to healthcare and domestic settings
 - The UK Health Security Agency has produced and updated [recommendations for the use of pre- and post-exposure vaccination during a monkeypox incident](#)
 - This document contains background information regarding the Imvanex vaccine, recommendations regarding pre- and post-exposure vaccination, how to prioritize the vaccine stock, booster doses, and vaccine prescribing and administration
 - The UK Health Security Agency has produced a [monkeypox contact tracing classification and vaccination matrix](#) to help guide follow-up and vaccination advice for individuals who have had varying levels of exposure risk with confirmed cases of monkeypox
 - The UK Health Security Agency has produced guidance regarding the [cleaning of sex-on-premises venues](#) in light of the monkeypox virus outbreak
 - The UK Health Security Agency has produced [guidance regarding monkeypox in prisons and places of detention](#)
- Clinical presentation**
- The UK Health Security Agency has produced [guidance regarding case definitions](#) of possible, probable, and confirmed cases of monkeypox
- Diagnosis**
- The UK Health Security Agency has produced guidance for [collecting, submitting, and processing of samples](#) for the diagnosis of monkeypox

	<ul style="list-style-type: none"> • The rare and imported pathogens laboratory (RIPL) at the UK Health Security Agency Porton Down has been designated as the diagnostic laboratory for monkeypox <ul style="list-style-type: none"> ◦ Professionals are being asked to consult with the imported fever service before sending blood samples for testing • Public Health England has produced a monkeypox guidance document for primary care which provides information on transmission, clinical features, patient assessment, and infection prevention and control <p>Treatment</p> <ul style="list-style-type: none"> • The UK Health Security Agency notes that the smallpox vaccine, cidofovir, and tecovirimat can be used to control outbreaks, but monkeypox treatment is mostly supportive • The UK Health Security Agency has released interim guidance about the de-isolation and discharge of monkeypox-infected patients, which pertains both to patients admitted to hospitals as well as those who manage symptoms at home • The UK Health Security Agency has produced guidance regarding home isolation for people who have been diagnosed with monkeypox infection <ul style="list-style-type: none"> ◦ Cases are being asked to isolate at home, if they are well enough, and to avoid contact with others until lesions have healed and scabs have dried
United States (U.S.)	<p>Biology</p> <ul style="list-style-type: none"> • According to the CDC, Monkeypox is a rare disease that is caused by infection with monkeypox virus, which belongs to the Orthopoxvirus genus in the family Poxviridae <p>Epidemiology</p> <ul style="list-style-type: none"> • As of 7 July 2022, the U.S. has reported a total of 605 confirmed monkeypox cases • The first human case of monkeypox was recorded in 1970 in the Democratic Republic of the Congo (DRC) during a period of intensified effort to eliminate smallpox • Since then, monkeypox has been reported in people in several other central and western African countries: Cameroon, Central African Republic, Cote d'Ivoire, Democratic Republic of the Congo, Gabon, Liberia, Nigeria, Republic of the Congo, and Sierra Leone • Transmission of monkeypox virus occurs when a person comes into contact with the virus from an animal, human, or materials contaminated with the virus • On May 18, 2022, a U.S. resident tested positive for monkeypox after returning to the U.S. from Canada. As of May 18, 2022, no additional monkeypox cases have been identified in the U.S. • The virus enters the body through broken skin (even if not visible), respiratory tract, or the mucous membranes (eyes, nose, or mouth) • Animal-to-human transmission may occur by bite or scratch, bush meat preparation, direct contact with body fluids or lesion material, or indirect contact with lesion material, such as through contaminated bedding • Human-to-human transmission is thought to occur primarily through large respiratory droplets <ul style="list-style-type: none"> ◦ Respiratory droplets generally cannot travel more than a few feet, so prolonged face-to-face contact is required • Other human-to-human methods of transmission include direct contact with body fluids or lesion material, and indirect contact with lesion material, such as through contaminated clothing or linens <p>Prevention and control</p>

- The [U.S. CDC](#) recommends that individuals should be vaccinated within four days from the date of exposure to prevent onset of the disease to prevent the onset of the disease, but if it is given between four to 14 days after exposure, the vaccination may reduce symptoms but not prevent the disease
- According to the [U.S. CDC](#)., there is currently a limited supply of JYNNEOS but more is expected in the coming weeks and months, and there is an ample supply of ACAM2000
 - Individuals are fully vaccinated after two weeks of the second dose of JYNNEOS, and four weeks after receiving ACAM2000
 - Vaccination strategies can include post-exposure prophylaxis (PEP), expanded PEP (e.g., targeting people who have certain risk factors), and PrEP (e.g., individuals who are at high risk such as clinicians and laboratory workers who handle specimens that might contain monkeypox virus)
- A recent [Morbidity and Mortality Weekly Report published by CDC](#) recommended the following vaccination for persons at risk for occupational exposure to orthopoxviruses:
- For Primary Vaccinations, the Advisory Committee on Immunization Practices unanimously voted in favor of the JYNNEOS vaccine as an alternative to ACAM2000
- For booster doses, ACIP unanimously voted in favor of the JYNNEOS booster vaccine after the 2-dose JYNNEOS primary series
- ACIP recommended that the JYNNEOS booster dose be administered every 2 years to persons working with more virulent orthopoxviruses and every 10 years to persons working with less virulent orthopoxviruses.
- For the option of transitioning from JYNNEOS for a booster dose in persons who had received primary vaccination with ACAM2000, ACIP unanimously voted in favor of recommending JYNNEOS boosters as an alternative to ACAM2000 boosters in persons who received ACAM2000 as the primary vaccine
- The report also states that the benefit/risk ratio should be considered when administering vaccination to special populations
- In the United States, [the two-dose Jynneos vaccine](#) is licensed to prevent smallpox and specifically to prevent monkeypox
- According to the [CDC](#), the following measures can be taken to prevent infection with monkeypox virus:
 - Avoid contact with animals that could harbor the virus (including animals that are sick or that have been found dead in areas where monkeypox occurs)
 - Avoid contact with any materials, such as bedding, that has been in contact with a sick animal
 - Isolate infected patients from others who could be at risk for infection
 - Practice good hand hygiene after contact with infected animals or humans (e.g., washing your hands with soap and water or using an alcohol-based hand sanitizer)
 - Use personal protective equipment (PPE) when caring for patients

Clinical Presentation

- In humans, the [symptoms of monkeypox](#) are similar to, but milder than the symptoms of smallpox
- Monkeypox begins with fever, headache, muscle aches, and exhaustion
- The main difference between symptoms of smallpox and monkeypox is that monkeypox causes lymph nodes to swell (lymphadenopathy) while smallpox does not
- The incubation period (time from infection to symptoms) for monkeypox is usually seven to 14 days but can range from five to 21 days, and the illness typically lasts for two to four weeks
- The development of initial symptoms (e.g., fever, malaise, headache, weakness, etc.) marks the beginning of the prodromal period

Diagnosis

- [Clinicians can recognize potential monkeypox](#) infection based on the similarity of its clinical course to that of ordinary discrete smallpox
- A feature that distinguishes infection with monkeypox from that of smallpox is the development of swollen lymph nodes (lymphadenopathy)
- Swelling of the lymph nodes may be generalized (involving many different locations on the body) or localized to several areas (e.g., neck and armpit).
- Shortly after the prodrome, a rash appears
 - Lesions typically begin to develop simultaneously and evolve together on any given part of the body
 - The evolution of lesions progresses through four stages—macular, papular, vesicular, to pustular—before scabbing over and resolving
 - This process happens over a period of two to three weeks

Prognosis

- The severity of illness can depend upon the initial health of the individual, the route of exposure, and the strain of the infecting virus (West African vs. Central African virus genetic groups, or clades)

Treatment

- According to the [U.S. CDC](#), there is currently no treatment available specifically for MPX infections, however there are medical countermeasures available through the Strategic National Stockpile (SNS) with limited available evidence on its effectiveness for the treatment of monkeypox such as: 1) Tecovirimat; 2) Vaccinia Immune Globulin Intravenous (VIGIV); 3) Cidofovir; and 4) Brincidofovir

Appendix 5: Experiences in Canadian provinces and territories related to available evidence about monkeypox [yellow highlights = newly added or revised content in this version of the living evidence profile]

Province/territory	Summary of experiences
Pan-Canadian	<p>Biology</p> <ul style="list-style-type: none"> • According to the Government of Canada’s website, monkeypox is a viral disease that can enter the body through broken skin, the respiratory tract, or the mucous membranes of the eyes, nose or mouth • The virus naturally occurs in Western and Central Africa, and the cessation of smallpox vaccination appears to have increased humans’ susceptibility to severe monkeypox <p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • The Public Health Agency of Canada reported a total of 358 cases of monkeypox in Canadian provinces and territories as of 6 July 2022, with 236 cases confirmed in Québec, 101 cases in Ontario, eight cases in Alberta, and 13 cases in British Columbia • Monkeypox can spread in three ways: 1) animals (e.g., rodents, primates) to humans; 2) person-to-person; and 3) through contaminated objects • Humans may also become infected by eating uncooked contaminated meat or through contact with body fluids from infected animals or humans • An infected pregnant women may also pass monkeypox on to their developing fetus • The virus is contagious between one to five days before the stage-two rash develops up until the scabs fall off and the skin heals • At a news conference on 3 June 2022, Canada’s Chief Public Health Officer, Dr. Theresa Tam, reported that a disproportionate number of the confirmed cases in Canada are among gay and bisexual men but warned that anyone can be potentially susceptible to the disease <ul style="list-style-type: none"> ○ She encouraged public health officials to learn from the experience of the HIV/AIDS epidemic and to involve communities that are most impacted right from the start ○ Officials have stayed clear of confirming the origin of monkeypox in Canada citing privacy and stigmatization concerns • In an announcement on 4 July 2022, the Public Health Agency of Canada (PHAC) noted that the possibility and extent of respiratory transmission is of monkeypox is “unclear at this time.” <p>Prevention and control</p> <ul style="list-style-type: none"> • Since monkeypox primarily spreads through close contact, people can lower their risk of contracting monkeypox by maintaining physical distance and using frequent hand hygiene and respiratory hygiene, such as masking <ul style="list-style-type: none"> ○ In the coming days, the federal government will release updated guidance for infection prevention and control considering the recent confirmed cases of monkeypox • The Public Health Agency of Canada has issued a travel health notice, last updated 20 June 2022, to practise enhanced health precautions when traveling to certain countries <ul style="list-style-type: none"> ○ Enhanced health precautions may include using personal protective equipment, delaying travel until risk is lower, avoiding higher risk activities, and additional vaccinations for certain groups

- On 8 June 2022, the National Advisory Committee on Immunization (NACI) released [interim guidance on the use of Imvamune](#), a third-generation smallpox vaccine, for post-exposure prophylaxis (PEP) against monkeypox:
 - A single dose of Imvamune may be offered to individuals with high-risk exposures of a probable or confirmed case of monkeypox, or in setting where transmission is occurring, ideally within four days of exposure
 - PEP should not be offered to individuals who already have a monkeypox infection
 - A second dose of Imvamune may be offered after 28 days of the first dose if continued risk of exposure is indicated
 - NACI also recommended Imvamune pre-exposure prophylaxis (PrEP) for adults at high risk of occupational exposure in a laboratory research setting and for special populations, such as individuals who are immunocompromised, pregnant, lactating, children and youth who are less than 18 years old, and individuals with atopic dermatitis based on exposure risk
- According to a [4 July 2022 news report](#), a total of 8,101 doses of IMVAMUNE vaccine have been administered in Québec since 27 May, and as of 30 June, nearly 6,000 people in Toronto have been vaccinated against monkeypox
 - [Vaccination also began in Alberta](#) on 4 July 2022
- Canada's Chief Public Health Officer, Dr. Theresa Tam, indicated that [negotiations are underway to procure more monkeypox vaccine](#) from the Danish manufacturer Bavarian Nordic
 - The manufacturer said in early June that PHAC had agreed to a US\$56 million, five-year contract to purchase IMVAMUNE vaccine, with expected delivery beginning in 2023

Clinical presentation

- The [Government of Canada describes the symptoms of monkeypox in two stages](#) that typically develop five to 21 days after exposure and last between two and four weeks:
- Stage one symptoms may include fever, headache, chills, swollen lymph nodes, muscle pain, back pain, joint pain, and exhaustion
- Stage two symptoms include a rash that develops on the face, extremities, or other parts of the body one to three days after the fever, and usually lasts between 14 and 21 days as it changes through different stages before it falls off as a scab

Diagnosis

- Diagnosis of monkeypox can be done by a healthcare provider, according to the [Government of Canada's website](#)
- Symptoms usually resolve within a few weeks and are often mild, but in rare cases, death can occur
- One recent [news report](#) indicated that the limited surveillance of monkeypox in Canada and the time it takes to diagnose and send samples for confirmation to the National Microbiology Laboratory in Winnipeg makes it likely that Canada is weeks behind in identifying the true scope of the spread of monkeypox in the country
- As of 25 May 2022, there were [16 confirmed cases of monkeypox in Canada](#), a large increase from the first case count only a week prior

Prognosis

- Vaccination with the smallpox vaccine within four days and up to 14 days after initial contact with an infected monkeypox case can [protect against monkeypox with greater than 85% efficacy](#)
- Canada's Minister of Health, Jean-Yves Duclos announced on 24 May 2022 that [Canada has a supply of Imvamune vaccines and therapeutics from the National Emergency Strategic Stockpile \(NESS\)](#) that they will maintain as they work on rolling out a response plan

	<p>Treatment</p> <ul style="list-style-type: none"> • Treatment for monkeypox is mainly supportive and there are no licensed antiviral drugs available to treat monkeypox • According to a Montreal news report, the federal government will be sending vaccines and other “therapeutics” to Québec to help the province address the recent outbreak of monkeypox
British Columbia	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • As of 14 June 2022, there are two cases of monkeypox in British Columbia • The British Columbia Centre for Disease Control maintains a webpage about monkeypox for healthcare providers with information about clinical presentation, transmission, management of suspected cases (including diagnosis and testing), infection prevention and control, and treatment • The British Columbia Centre for Disease Control also maintains a webpage about monkeypox for the public that contains information about the current situation, how it spreads, symptoms, what to do if you have been exposed, what to do if you become ill, and prevention and vaccination <p>Prevention and control</p> <ul style="list-style-type: none"> • The British Columbia Centre for Disease Control maintains a webpage about monkeypox for healthcare providers with information about clinical presentation, transmission, management of suspected cases (including diagnosis and testing), infection prevention and control, and treatment • On 20 May 2022, the Provincial Health Officer of British Columbia issued a notice of duty to report all suspected cases of monkeypox as per the Reporting Information Affecting Public Health Regulation of the <i>Public Health Act</i> • The British Columbia Centre for Disease Control has produced a factsheet with recommendations for Two-Spirit, gay, bisexual, transgender and queer communities <p>Clinical presentation</p> <ul style="list-style-type: none"> • The British Columbia Centre for Disease Control maintains a webpage about monkeypox for healthcare providers with information about clinical presentation, transmission, management of suspected cases (including diagnosis and testing), infection prevention and control, and treatment • The British Columbia Centre for Disease Control states that the disease generally occurs in two stages <ul style="list-style-type: none"> ○ The first stage often includes symptoms such as fever, chills, headache, swollen lymph nodes, body pain, and fatigue and lasts two to three weeks ○ The second stage typically starts one to five days after the first stage and includes rashes as well as sores that change over time <p>Diagnosis</p> <ul style="list-style-type: none"> • The British Columbia Centre for Disease Control maintains a webpage about monkeypox for healthcare providers with information about clinical presentation, transmission, management of suspected cases (including diagnosis and testing), infection prevention and control, and treatment <p>Treatment</p> <ul style="list-style-type: none"> • The British Columbia Centre for Disease Control maintains a webpage about monkeypox for healthcare providers with information about clinical presentation, transmission, management of suspected cases (including diagnosis and testing), infection prevention and control, and treatment

Alberta	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • As of 3 June 2022, one case of monkeypox has been confirmed in Alberta • The Chief Medical Officer’s 3 June 2022 notice stresses that the risk is low to the general population, but the virus can affect anyone in close contact with a case (and is not limited to spread via intimate sexual activities) • The Chief Medical Officer’s 20 May 2022 notice for Alberta Health Services medical staff included a note about monkeypox <ul style="list-style-type: none"> ○ The note included background information about monkeypox and reminded physicians about mandatory reporting for rare or emerging communicable diseases and the need to notify the Medical Officer of Health regarding any suspected cases of monkeypox • The Government of Alberta has produced a factsheet about the Monkeypox virus outbreak that covers the following topics: transmission, symptoms, prevention (both on an individual and community level), testing, treatment, vaccination, and travelling outside Canada • The Alberta Medical Association is hosting a webinar on 29 June 2022 about Monkeypox in Alberta for community physicians <p>Prevention and control</p> <ul style="list-style-type: none"> • The Alberta Health Service has produced vaccine information sheets for the Imvamune Monkeypox/smallpox vaccine (Bavarian Nordic) targeted at both clinicians as well as a separate sheet targeted at the public <p>Diagnosis</p> <ul style="list-style-type: none"> • The Public Health Laboratory and Alberta Precision Laboratories produced a memo for all physicians and clinicians regarding testing for Monkeypox, which contains in-depth background information, information about the virological diagnosis of Monkeypox, what to do if clinicians suspect a patient has Monkeypox, and details about specimen collection
Saskatchewan	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • Monkeypox does not spread easily from person to person and is primarily spread through prolonged face-to-face close contact, touching bodily fluids of a person who is sick with the disease, or from exposure to contaminated objects <p>Prevention and Control</p> <ul style="list-style-type: none"> • The Saskatchewan Health Authority released Interim Infection Prevention and Control Guidelines for monkeypox • Saskatchewan will be offering vaccines offering protection against monkeypox to close, high-risk contacts of an infected person if cases are found in the province
Manitoba	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • Spread occurs when a person comes into close contact with an infected animal, human, or materials contaminated with the virus <p>Clinical presentation</p> <ul style="list-style-type: none"> • Symptoms include fever, malaise, headache, backache, chills, weakness, and swollen lymph nodes <p>Diagnosis</p> <ul style="list-style-type: none"> • Manitoba is actively monitoring for monkeypox cases, although none have been identified yet <p>Treatment</p> <ul style="list-style-type: none"> • Treatment of monkeypox is mainly supportive, but in severe cases antivirals may be considered

Ontario

Biology

- [Monkeypox](#) is an orthopoxvirus caused by the Monkeypox virus

Epidemiology (including transmission)

- Monkeypox can be transmitted from animals to humans or by contact with [infected lesions, skin scabs, body fluids, or respiratory secretions](#), and by being in contact with [materials contaminated with the virus \(clothing, bedding\)](#)
 - Human-to-human transmission of monkeypox is uncommon, but it may occur through respiratory droplets or contact with bodily fluids, skin lesions, and contaminated materials
- There is [possible transmission](#) during the prodromal period (when early symptoms such as fever, malaise, and headache appear) and the potential for airborne transmission
- [A Toronto report](#) dated 7 June 2022 also noted that monkeypox can be transmitted from contact with infected animals through bites/scratches and wild game meat preparation
 - It is not as transmissible as COVID-19
 - Monkeypox is most infectious from onset of initial lesions until the scabs have fallen off and new skin is present
- [A report by Public Health Ontario](#) dated 13 June 2022 indicated that transmission from mother to infant may occur via vertical transmission across the placenta (which can lead to congenital monkeypox) or during close contact after birth
- **As of 4 July 2022, there have been 101 confirmed cases of monkeypox in Ontario, whereby 84.2% of confirmed cases were reported by Toronto Public Health and 100% of cases are male**
 - There are 8 probable cases (100% are male)

Prevention and control

- The [Ontario Monkeypox Investigation Tool](#) was created to record patient information and prevent future illness caused by Monkeypox
- People can [lower their risk of exposure](#) by maintaining physical distance, frequently washing their hands, and wearing masks
- [Precautions](#) should be taken until all scabs have fallen off and new skin is present
 - The airborne/droplet/contact precautions should be used: measures include airborne isolation rooms (AIR) with negative pressure ventilation and when AIRs are not available, a patient can be placed in a single room with the door closed with a single toilet
 - If these measures are not feasible, patients should wear a medical mask and cover exposed lesions with clothing, sheets, or a gown, especially during transport across hospital facilities
 - Healthcare workers should wear a fit-tested and sealed N-95 mask, gloves, gown, and eye protection (face shield or goggles)
 - Soiled linens should be cleaned to prevent dispersal of microorganisms
 - Waste (dressings) should be disposed according to facility-specific guidelines for infectious waste
 - Healthcare-grade cleaning agents with a Drug Identification Number (DIN) should be used
- [Precautionary measures](#) include isolation, wearing PPE, good hand hygiene, avoiding contact with animals that could carry the virus, avoiding contact with bedding or laundry in contact with sick animals or humans
 - Standard household cleaning disinfectants can be used to kill the virus
 - Talking to sexual partners about sexual health and using barriers such as gloves and condoms
 - Avoid sharing toothbrushes, sex toys, and drug use supplies

- Avoid prolonged face-to-face contact, especially indoors
- Stay home if you are sick, and encourage others to do the same
- [Asymptomatic patients](#) can be managed in a primary care setting, vaccination clinics and other outpatient settings such as sexual health clinics
- A [report by Public Health Ontario](#) dated 13 June 2022 indicated that self-isolation must be maintained until all scabs have fallen off, new skin is present, and they have been cleared by their public health unit (no longer considered infectious)
 - An AIIR is not required for specimen collection
 - It is recommended that hand hygiene facilities be available in laundry areas, and that clothes from monkeypox cases be machine washed using 70-degree Celsius hot water and regular laundry detergent
 - Routine environmental disinfection must occur in emergency rooms and outpatient settings, inpatient rooms, and shared showering facilities
- A [technical report by Public Health Ontario](#) dated 28 May 2022 describes interim case and contact management guidelines for local public health units based on information from selected public health organization such as the CDC, the United Kingdom Health Security Agency, and the WHO
 - For those self-isolating, it is recommended to cover skin lesions by wearing long clothing, designating one person to care for the person who is self-isolating
 - It is recommended to wear gloves when handling laundry, to not shake or agitate soiled laundry dispersing infectious particles
 - Contaminated dressings and bandages should not be disposed of with household garbage or in landfills, so consider using a biohazard/environmental remediation company to transport waste safely to the hospital for safe processing
 - A detailed guide to assessing risk of exposure is provided in the document
- A [report dated 21 June 2022](#) indicated that the Imvamune vaccine is approved in Canada as prophylaxis for protection against monkeypox pre-exposure or post-exposure to monkeypox (post-exposure vaccines should be given within 4 days but can be given up to 14 days after last exposure)
 - Based on Ontario Ministry of Health guidelines, Imvamune vaccine clinics are available for people 18 years or older who are transgender or cisgender who self-identify as a man and belong to the community of gay, bisexual and other men who have sex with men as well as one of the following:
 - Diagnosed with a bacterial STI in the past 2 months
 - Had 2 or more sexual partners within the past 21 days or are planning to
 - Attended venues for sexual contact within the past 21 days or plan to or work/volunteer in these settings
 - Had casual or anonymous sex in the past 21 days
 - Engage in sex work or plan to, and their sexual contacts
 - Cis-gender women are not eligible for the vaccine unless identified as a close contact of a case
- [Prior vaccination against smallpox](#) provides some cross-protection to monkeypox
- A [report by the Ontario Ministry of Health](#) dated 28 May 2022 provides guidance for the Imvamune vaccine as post-exposure prophylaxis (PEP)
 - Imvamune is a live 3rd generation replication deficient smallpox vaccine, developed to provide an alternative for the vaccination of immunocompromised individuals with atopic dermatitis who couldn't receive replicating smallpox vaccines

- Based on extrapolation from animal studies and smallpox vaccines in humans, a 0.5 mL dose of Imvamune within 4 days of exposure may prevent infection or lessen disease severity
- It was authorized by Health Canada in 2020 for active immunization against smallpox, monkeypox, and related orthopoxviral infections in adults at high risk of exposure from a confirmed or probable case
- Individuals who have been in the same premises as a confirmed or probably case but with no known risk exposure are not recommended to receive PEP
- There is limited data on the use of Imvamune in pregnancy and for individuals with severe immunosuppression, and the vaccine is not authorized for use in individuals under 18 years of age (although it has been offered to children in previous U.K. monkeypox incidents)
- It is not recommended to co-administer Imvamune with other vaccines and to reschedule other vaccines until 14 days after Imvamune; however, Imvamune should not be delayed for individuals who have recently received another vaccine
- Side effects of Imvamune include pain, erythema, induration, and swelling at injection site, and fatigue, headache, myalgia, and nausea, and reactions resolved within the first 7 days following vaccination
- Older generations of smallpox vaccines have been associated with myocarditis, while cardiac events of special interest (AESIs) were found in 1.4% of Imvamune recipients
- Imvamune should be stored frozen or and thawed at room temperature, with more details indicated in [this report](#)
- A [report by the Ontario Ministry of Health](#) dated 14 June 2022 provides Imvamune guidelines for healthcare providers
 - The report provides an overview of using Imvamune in special populations: clinical trials have included people living with HIV, there is less experience in individuals with severe immunosuppression; no clinical trials have been conducted in pregnant individuals, although approximately 300 pregnancies have been reported to the manufacturer with no safety issues, and there is no data on whether the vaccine is excreted in breastmilk although this is unlikely since the vaccine is nonreplicating; the vaccine has not been studied in youth under 18 although it has been given to children as PEP in the U.K. for monkeypox; people with atopic dermatitis may have more intense and frequent reactions after vaccination

Clinical presentation

- [Most people recover from monkeypox within two to four weeks](#), although severe illness can occur in some individuals
 - [Symptoms](#) include fever, chills, headache, myalgias, swollen lymph nodes in the neck and groin area, fatigue, and rashes (on face, limbs, palm of hands and soles of feet, mucous membranes like mouth and genitals) that follow one to three days after the onset of other symptoms
 - The [Ontario Ministry of Health](#) recorded other symptoms including chills/sweats, back pain/ache, sore throat/cough, coryza (inflammation of the mucous membrane of the nose), and distress
 - [Public Health Ontario](#) stated that in the 33 confirmed cases as of 21 June 2022, the most commonly reported symptoms included rashes, oral/genital lesions, swollen lymph nodes, headache, fever, chills, myalgia, and fatigue
- An [updated report](#) dated 13 June 2022 indicates that the incubation period averages 6-13 days (range 5-21 days), during which individuals are not considered infectious
- [The rashes or lesions](#) often begin on the face and spread to other parts of the body, and generally appear [1-3 days after fever](#), though in some recent cases, it appears before fever or other symptoms
- In [recent cases](#), the rashes appear around the mouth, genital or anorectal areas

Diagnosis

	<ul style="list-style-type: none"> • Monkeypox can be diagnosed with symptoms, a laboratory test, and risk factors such as exposure to a monkeypox case as well as travel to a region with a confirmed case • Last updated on 17 June 2022, Public Health Ontario released a set of comprehensive testing indications related to specimen collection and handling, preparation of specimen prior to transport, requisitions and testing kit ordering, test frequency and turnaround time, test methods, PCR test interpretation, as well as reporting guidelines <p>Prognosis</p> <ul style="list-style-type: none"> • The most infected people will recover on their own within 2-4 weeks, and that the infection is rarely fatal <p>Treatment</p> <ul style="list-style-type: none"> • The report also mentioned Tecovirimat (TPoxx) treatment in Canada (three 200 mg capsules twice daily for 14 days), which is not authorized for monkeypox, but can be given by a licensed healthcare professional for severe monkeypox infections
Québec	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> • The Ministry of Health and Social Services in Quebec states that monkeypox contagiousness is limited compared to other viruses like the flu and COVID-19 because it is contracted by prolonged and close contact with an infected person • As of 29 June 2022, 211 cases of monkeypox have been reported in Quebec <p>Clinical presentation</p> <ul style="list-style-type: none"> • Infected people have mild symptoms, disappearing after 14-21 days and do not require hospitalization • Symptoms include fever, headache, muscle aches, back pain, swollen lymph nodes, chills, and fatigue • Rashes also occur often on the face and may spread to other parts of body such as the genitals <p>Prevention and control</p> <ul style="list-style-type: none"> • People who think they are infected should self-isolate at home, wear a mask, cover lesions, and avoid direct contact with others • They should also monitor themselves for symptoms for 21 days and avoid sexual relations until 21 days after last contact <p>Diagnosis</p> <ul style="list-style-type: none"> • The Ministry of Health and Social Services in Quebec confirmed the first two cases of monkeypox on 19 May 2022, and 20 other cases of genital ulcer lesions are under investigation • As of 19 May 2022, all suspected cases have affected men who have sex with other men <p>Treatment</p> <ul style="list-style-type: none"> • Antivirals could be an option, but their clinical usefulness must be evaluated before recommended • A report last updated on 20 May 2022 stated that high-risk contacts of a confirmed or probably case of monkeypox may be vaccinated with a single dose within 4 days of exposure, and a second dose only if risk of exposure is present 28 days later • In Quebec, a vaccine is available to protect against monkeypox, which can be administered before or after exposure, but the vaccine is reserved for people targeted by public health authorities <ul style="list-style-type: none"> ○ A post-exposure vaccine may be given within the past 14 days if you have had: direct contact with skin, fluids, or items that have been contaminated with fluids or secretions of someone with monkeypox symptoms, or prolonged close contact with someone with monkeypox symptoms (3 or more hours less than 1 metre away without a mask) ○ If a person has symptoms of monkeypox at time of vaccination, the post-exposure vaccine may not be given

	<ul style="list-style-type: none"> ○ A pre-exposure vaccine may be giving if you are a man who is having or will have sex with another man in Montreal in the following situations: sex with more than one regular partner, sex in a place where sexual activities take place, sex in exchange for money, goods, or services ○ Staff and volunteers in a social setting or event where sexual activities take place may also receive the pre-exposure vaccine ○ Men with one regular sex partner do not need to receive the pre-exposure vaccine
New Brunswick	<p>Prevention and control</p> <ul style="list-style-type: none"> ● New Brunswick is staying informed on the monkeypox outbreak to better prepare if the virus arrives in the Maritimes <p>Diagnosis</p> <ul style="list-style-type: none"> ● New Brunswick identified a suspected case of monkeypox, but the patient was not assessed until after symptoms had passed
Nova Scotia	<p>Prevention and control</p> <ul style="list-style-type: none"> ● Nova Scotia is actively monitoring the monkeypox outbreak but to date has no reported cases
Prince Edward Island	<ul style="list-style-type: none"> ● Prince Edward Island is actively monitoring the monkeypox outbreak, but to date has no reported cases
Newfoundland and Labrador	<ul style="list-style-type: none"> ● Newfoundland and Labrador is actively monitoring the monkeypox outbreak, but to date has no reported cases
Yukon	<p>Epidemiology (including transmission)</p> <ul style="list-style-type: none"> ● To date, there are no reported cases in Yukon <p>Prevention and control</p> <ul style="list-style-type: none"> ● The Government of Yukon is actively working with Public Health Agency of Canada and other public health partners to investigate the spread of monkeypox and assess the situation
Northwest Territories	<ul style="list-style-type: none"> ● None identified
Nunavut	<ul style="list-style-type: none"> ● None identified
